Exhibiting Vegetables.—The remarks on this subject by Mr. Chapman, page 446, issue September 11, are interesting. I do not think it is difficult to find a reason why vegetables are not more prominent at shows, especially this year. The reason is lack of labour, coupled with a lack of interest by employers. There is no disputing the fact that to produce vegetables in the manner alluded to by Mr. Chapman means an outlay in seed, labour and space, and as long as employers obtain what they require for their personal use, the matter ends. When this occurs, a gardener is much hampered in his resources, even though he would be and is enthusiastic in his endeavours to emulate the few whose produce appears on the exhibition tables at leading shows. If these reasons are correct, then there is small prospect of an increase in the number of exhibitors of vegetables in the near future. It is quite true that prominent men in the vegetable world can be counted on the fingers of two hands; more is the pity, because I am positive there is a future before any youthful aspirant in this phase of horticulture who has cultural knowledge, convenience, and an aptitude for the raising of new varieties of vegetables. Although many may say we have quite enough Peas, Potatoes and so forth, there is ample room for more variety in almost every section. There has been, and always will be, a difference of opinion as to what constitutes quality in vegetables; so many persons (mainly those who do not grow them) argue that a large Onion is not equal to a small one, and in the same manner, that large-podded Peas are not equal to those bearing half the number of Peas in a pod. True, Cauliflowers, Cabbages, Vegetable Marrows and Carrots may be grown so large as to be objectionable, but

no expert would err in this manner. Arranging the various collections attractively is important, and no doubt this phase is much further developed now than formerly, thanks mainly to Mr. Beckett, who can safely be called the pioneer in this respect. When one thinks of the crude methods of exhibiting thirty years ago, when all collections were crowded into a flat box, where they could barely be seen, and compares them with what can be seen at the leading shows, especially those displays under the auspices of the Royal Horticultural Society, one wonders how such could have been tolerated so long.—E. MOLYNEUX, *Swanmore*.

The Water Elder.—Just now (the second week in September) there is nothing more beautiful in the garden than the thickly berried branches of the Water Elder (*Viburnum Opulus*), of which I send some examples. They have not yet attained their full beauty, for in a week or ten days their fine red colouring will be deeper still and the berries will have a translucent quality like that of ripe Red Currants. The berries are unusually large and abundant this year; the end of every twig is heavily loaded, and the bushes would be broken down if we had not propped them in time. In some of the bunches of fruit from a single cyme there are as many as eighty berries, each berry having a diameter of fully three-eighths of an inch; some are nearly half an inch. It is a native shrub or small tree, growing in damp ground and by wet ditches in water-meadows, but is so accommodating that it seems to thrive equally well on our dry, sandy hill. Everyone knows the Guelder Rose (the garden variety of the same shrub), with its great white balls of bloom in May. The wild plant has a flat bloom, with the conspicuous sterile florets forming an outer ring to the smaller, less showy fertile florets within. In the Guelder Rose all the florets are sterile, and as they are larger than the fertile, the flower has to take a ball form in order to give them space. Every garden should have both; the Guelder Rose for early summer bloom and the Water Elder for glory of autumn fruit.—G. JEKYLL.

Daffodil Olympia.—This, figured and described in *THE GARDEN* for September 11, page 443, is certainly a monster and striking variety, but I consider it rather too much to say that the name of Van Waveren will go down to posterity because of Olympia. Even the most ordinary individual objects to the wasting, pinched appearance of three of the perianth segments. I admire the ragged trumpet, but the perianth takes away half its beauty. If Van Waveren is to be remembered by any one of his Daffodils in commerce, surely Cornelia holds the palm. To me Cornelia is a gem among the lower-priced trumpets, and last season six bulbs in a clump in my front garden produced twelve flowers of such striking superiority

that even the most casual passers-by remarked upon it. Doubtless many thought it was Emperor or some such variety that is popular, but all with any glimmer of garden knowledge instantly realised that it was something out of the ordinary.—T. A. W.

How to Store Vegetable Marrows.—The crop of this most useful vegetable comes in when there are numerous summer and autumn vegetables for the table. Many people do not know that Marrows will keep very well, and so they cut and use them, allowing the more valuable Peas, Beans, &c., to grow too tough and coarse to eat. To store Marrows is easy, and here from extensive trial we find the following method good: Cut the fruit when it is

A WELL-BERRIED BRANCH OF THE WATER ELDER.

just turning yellow (a sign of ripeness), on an afternoon when it is dry. If at all damp, wipe with a cloth. Spread out the fruits on a shelf in a light and cool airy room, and turn them over occasionally during the next month or two. The room we use gets afternoon sun, and the Marrows are not harmed in the least if the sun reaches them. We find they will keep till nearly Christmas, though, of course, they are used as required in the autumn and winter months. The only difference is that the flesh of the stored fruit is yellower than that cut straight from the bed and used, but the flavour is not impaired in the slightest. I hope this advice may be useful to readers who are not "in the know."—E. T. ELLIS.

STORING VEGETABLES FOR WINTER USE.

A CORRESPONDENT who has a large, dark cellar at his disposal asks for information concerning the storing of vegetables therein for use during the winter months. For a number of vegetables a cellar is quite a good store. It is generally frost-proof except in very severe and prolonged spells, and even then can usually be rendered suitable by covering any vegetables that are susceptible to frost with coarse mats or sacks, taking care, however, to remove these immediately all danger is past.

Undoubtedly the most important vegetable to be stored for winter use is the Potato, and for this a dark, frost-proof cellar possesses several advantages over the outdoor clamp, though many growers prefer the latter. In the cellar, however, the Potatoes are always available for use, whereas in very frosty weather it would be dangerous to break open the clamp. Also, owing to the fact that the tubers are kept dry, any disease that is present will not develop so rapidly as under the damper conditions that exist in the outdoor store. Before placing Potatoes in a cellar they should be exposed to wind and sun for a few hours. Not only does this dry up external moisture, but appreciably hardens the skins. The tubers are best placed in one heap, keeping them away from the wall of the cellar, so that, if necessary, mats or straw can be placed between them and the wall. A little fresh air-slaked lime shaken between the Potatoes as they are stored will assist to dispel unwanted moisture, and possibly prevent the spread of disease. The cellar must be well ventilated for two or three weeks after the Potatoes are placed in it.

Carrots, Beetroots and Turnips can all be successfully stored in a cellar, and will keep fresh and good for months if properly managed. Unlike Potatoes, they do not need preliminary drying. It is essential, however, that all the leaves be cut off, otherwise they will decay. Carrots and Turnips can be cut close to the root, but with Beetroots it is advisable to leave about an inch of the leaf-stalks. Where only comparatively small quantities of each are required, it will be found more convenient to store them in flat boxes, such as empty champagne cases or egg cases. A layer of sand or finely sifted earth ought to be first placed in the box; then a layer of roots, packed in neatly and closely; then another layer of sand or earth, the process of alternate layers being repeated until the box is full. Of course, a heap could be formed in a similar manner on the floor, but the boxes are much cleaner and more convenient. The use of sand or earth in this way prevents the roots

shrivelling and preserves their flavour. Salsify, Scorzonera and Celeriac are other vegetables that can be successfully treated in the same way. So also could Jerusalem Artichokes and Parsnips, but both are best left in the ground where they are growing, sufficient being lifted for use as required. Where this plan is adopted, however, it will be necessary to cover the beds with a thick layer of straw, bracken, or other dry rubbish during very frosty weather, otherwise it will be impossible to lift the roots when the soil is frozen hard.

A cellar is not, usually, a good place in which to store Onions. These keep best when tied in bunches or ropes and hung in a light, airy shed, but protected from frost. If bunching or roping cannot be adopted, the Onions should be laid out thinly in shallow boxes or trays. Whichever method is adopted, it is essential that they be given plenty of fresh air. Leeks and Celery keep best where they are grown if given protection from severe frosts. Both may, however, be successfully stored for some weeks in moist earth or sand in a cellar. The leaves should be trimmed off, but the roots left intact and stored as advised for Carrots, Turnips and Beetroots. Cauliflowers that are ready for cutting may be kept good for several weeks if lifted with a good mass of roots to each. The roughest outside leaves ought to be removed and the roots embedded in moist earth, which, for convenience, may be in a large, flat box. It must be remembered, however, that Cauliflowers, in common with other members of the Brassica family, emit a rather pungent odour that would probably be unpleasant in a cellar.

Essential points to remember in storing all kinds of vegetables are to see that they are quite free from any disease or signs of decay; that Cauliflowers, Celery and Leeks are dry when put into the store; and that frequent inspection of these succulent kinds is desirable so that any decay which appears can be promptly removed.

LATE-FLOWERING BUDDLEIAS.

BUDDLEIA VARIABILIS is one of the most attractive of late-flowering shrubs. It was first discovered by Professor Henry in the mountains north of Ychang in 1893, and few gardens are now without this ornamental plant or one or more of its beautiful varieties. In general appearance it little resembles the well-known Orange Ball (*B. globosa*), which usually flowers in great profusion earlier than this, when its rich orange, honey-scented blossoms form a striking feature; whereas the flowers of *B. variabilis* are arranged in elongated, pyramidal-shaped racemes, and, as the specific name indicates, are somewhat variable, but usually pinkish lilac with yellow throat.

There are several varieties, but two of the best are *B. v. veitchiana*, with large, handsome spikes of flower, and *B. v. magnifica*, which is still larger and of a much deeper colour. They appear to be a great attraction for butterflies, which are constantly to be found on them, and undoubtedly this is one of the means by which pollination is assisted. These shrubs should be cut back hard in spring.

GRAPE VINES IN EARLY AUTUMN.

AFTER expending much thought and labour on the watering, feeding and training of the Vines from spring to the end of the summer months, it is very annoying to lose some of the Grapes through not knowing how to manage the structure in the autumn. An amateur cultivator said one day lately, "I have some Black Hamburg Grapes; the other morning I noticed a few of them were cracked; again, as each day passed, more berries cracked. What was the cause?"

The cracking was caused by too much atmospheric moisture and lack of ventilation. If this

were started sufficiently early and the crop is not too heavy.

If there is much colouring necessary after the first week in October, the process is very slow and rarely quite satisfactory. A black Grape, when perfectly coloured, should not show red in the least when a lighted candle is held behind the bunch at night. Every berry should show a deep purple-black.

Very careful ventilation and a little fire-heat at night should be the rule if the berries are not finished by September 25. Every day from that date onwards is of much importance.

Watering.—Feeding should cease after the berries are three-parts coloured, but some watering with clear water is necessary. The border soil must not be allowed to approach dryness; keep it in a medium state of moisture, and, when water

is needed, give it in sufficient quantity to percolate through to the drainage, applying it early on a very fine day.

The Leaves and the Laterals.—The welfare of the crop for next year must be a matter for consideration now. All surplus shoots must be cut off while they are young; healthy Vines will continue to produce these small sublaterals until the end of October. If left on the Vines they would obstruct the light and the passage of air through the foliage, and so interfere with the due ripening of the basal buds on the side shoots, which contain the embryo fruit for next year's crop. G. G.

A BEAUTIFUL PINE.

PINUS ARMANDII.

This ornamental Chinese Pine is coning quite freely at Kew. It has now been in cultivation in this country about eighteen years, the trees being large enough to judge of their value for the beautifying of our pleasure grounds and parks. Herbarium specimens had been collected by previous travellers in China, but the honour of first introducing the tree to British gardens belongs to Mr. Augustine Henry, who forwarded seeds to Kew in 1897. The trees raised from these seeds are now about nineteen feet in height, and produced cones for the first time in 1909. There are several cones on one of the trees this year containing, apparently, good seeds. A French missionary, Père Farges, sent seeds to M. Maurice L. de Vilmorin in 1895, and more

recently Mr. E. H. Wilson consigned seeds to the Arnold Arboretum, so that young trees are now fairly easy to procure. *P. Armandii* is one of the five-leaved Pines. In appearance the tree resembles the Himalayan or Bhotan Pine, *P. excelsa*, and *P. Ayacahuite*, the Hickory Pine of Mexico. The cones of *P. Armandii* are shorter and broader than either of the two named, cylindrical, 6 inches to 8 inches long, and 3 inches to 4 inches in diameter. The leaves are shorter than those of *P. excelsa*, rather lighter in colour, and 4 inches to 6 inches long. *Armand's* Pine is widely distributed on the mountains of Western China, where it reaches a height of 50 feet to 60 feet. Altogether it promises to become a very ornamental Pine, particularly for lawn specimens, the rich green grass forming a pleasing foil to the silvery hue of the leaves.

PINUS ARMANDII. A NEW AND ORNAMENTAL PINE NOW CONING AT KEW.

cultivator had left the top ventilators open a little all night and a chink of air on at the front, and then opened all the ventilators more very early in the morning, he would have lost no berries of this variety through cracking, even if the atmospheric moisture had been too great. After the Grapes are ripe, only sufficient atmospheric moisture should be maintained to keep the leaves in a healthy condition; and if amateur cultivators, generally, will pay close attention to these details, they will not lose the fruits of their labour.

The Colouring of Late Grapes.—Few late black Grapes colour satisfactorily after the second week in October. To keep long and well, black Grapes, such as Alicante and Gros Colmar, should be thoroughly coloured by September 25. Usually, the process of colouring is very steady and complete by the date named if the Vines

THE JAPANESE WIND- FLOWERS.

IN the waning days of autumn, when the morning and evening mists have enshrouded the flowers of the outdoor garden and, in too many instances, marred their beauty, we appreciate those that come out of the ordeal unscathed. Among the most beau-

tiful of these are the Japanese Windflowers or Anemones, tall yet graceful flowers, quite unlike the dainty little native species that bespangles the greensward of our coppices in the gusty days of spring. These Japanese Anemones, by their very stature and bearing, are admirably adapted for grouping in the herbaceous border, in large lawn beds, the edges of shrubberies, or by the side of a pond or lake. They are never seen to better advantage, particularly the varieties with white blossoms, than when massed, in large bold groups, with a background of dark green foliated trees, these serving to accentuate the glistening purity of the daintily poised blossoms. When to the trees water is added, in which the flowers are reflected with a shimmer of light and shade, we begin to realise how indispensable these hardy plants are in the garden at this season. Nor must we overlook their usefulness for cutting. It is almost impossible to arrange them inartistically, their long stems and light, graceful flowers enabling the veriest tyro to create a picture of sublime beauty with these and autumn foliage.

Fortunately, the cultivation of the Japanese Anemones does not present any great difficulties. What they do appreciate is deeply cultivated and well-manured soil, and that with a good proportion of clay in it. One is often asked to name plants that will thrive in clay soil, and the Japanese Windflower is one of the best.

As the roots are long and thick, with but few fibres, transplanting is not advisable more often than is absolutely necessary; indeed, a good rule to follow is to disturb the plants as little as possible. In forming new beds or groups in borders, the planting may be done in late autumn or early spring, and pieces of root with as many fibres as possible should be given preference to those of a less fibrous character.

Contrary to a widespread belief, the original species has rose-coloured flowers with large, bold foliage, and a very useful plant it is. A variety named Honorine Joubert has pure white flowers, and is still one of the best for general purposes. Others with white blossoms are Whirlwind, very large and semi-double; and sylvestris, smaller and earlier, with dwarfer habit. There are several beautiful varieties with pink or rose coloured flowers, notably, Queen Charlotte, very large;

close association with Bulrushes and Sedges. The botanical name of the Tawny Balsam is *Impatiens fulva*, and although it is not a British plant in the strict sense of the term, it is an estray that has so far naturalised here within the last half century that it is now spreading rapidly in certain localities. Its singularly pretty flowers, borne on slender stalks and nodding in the breeze, cannot fail to attract attention. The flowers are orange-coloured, heavily marked with reddish

brown spots, with the open mouth of the horn-shaped sepal turning inward. The leaves are oval or ovate and coarsely toothed. From a botanical point of view, the most interesting feature of this *Impatiens*—and the same applies to other species—is seen in its wonderful fruits or seed-pods. These, when ripe, are pear-shaped and turgid, and if gently touched the seeds are discharged with surprising force, owing to the elasticity of the valves of the seed-pod. This peculiarity has given our native species the appropriate name *I. Noli-metangere* or Touch-me-not, while the very name *Impatiens* is derived from impatient, in reference to the elasticity of the valves of the seed-pod. The Tawny Balsam, although so much at home in and around our waterways, is really a native of North America, while the yellow Touch-me-not, *I. Noli-metangere*, grows wild in various parts of Europe.

There is another *Impatiens* often seen in cottage gardens and growing anything from 5 feet to 10 feet in height; the flowers are purple or rose and sometimes almost white. This is *Impatiens Roylei*, once figured in the *Botanical Magazine* as *I. glandulifera*, which it closely resembles. It is an attractive plant, but owing to its rampant growth is apt to become a nuisance if left unchecked in the flower garden and shrubbery. All of the *Impatiens* named are hardy, and all of them annuals. Seed may be sown

either this month or in the spring, and once these interesting annuals are established, self-sown seedlings may be relied upon in succeeding years.

The garden Balsam, *I. Balsamina*, with flowers quite as double as a perfect *Camellia*, requires to be raised in frames and transplanted. If given a rich and highly manured soil, it is inclined to make very sappy growth at the expense of blossom. The flowers are variously striped and spotted, and range in colour from crimson to white, rose, buff, mauve and violet.

C. Q.

JAPANESE ANEMONE QUEEN CHARLOTTE WITH LARGE PINK FLOWERS.

rosea, semi-double; Autumn Queen, *crispifolia*, *elegans* and *Lady Ardilaun*.

NOTES ON HARDY BALSAMS.

ALONG the banks of the Mereway near Twickenham, large colonies of the Tawny Balsam may be seen flowering at the present time. The plants, attaining a height of about four feet, are growing both on the dry banks and by the water's edge in marshy ground and in

SEASONABLE NOTES ON CARNATIONS.

THE time has again arrived when Perpetuals must be transferred to the structure in which they are to bloom during winter and spring. It is needless to remark that the pots should be scrubbed and the wood-work and glass of the Carnation-house cleaned. Few of us neglect these simple sanitary operations. Shoots that require tying should be seen to, and if the soil requires it, a sprinkling of Carnation manure be applied to the surface soil of each plant. One of the greatest mistakes where continuous bloom is expected is to arrange the plants close together. It is true that close grouping makes a more effective display through the late autumn months, but the later flowering shoots are so weakened that they are really worthless; whereas, given ample space and light, these will be almost as vigorous as the shoots formed during summer. Abundant ventilation while the weather permits is also important. It is very remarkable that there are still people who treat Carnations as semi-tender plants, and even through the summer months in northern parts there are growers who shut down the ventilators nightly, and as a result disappoint their hopes without knowing whence the disappointment has proceeded.

Every Carnation grower knows how very important it is that the supply of water shall be regulated with the greatest nicety, and that a workman who errs in applying slightly too little does infinitely less harm than he who goes to the opposite extreme. Much the same applies to manurial dressings. A little may be very effective in increasing the size of bloom and deepening the colour, while a little too much will produce flabby petals and split calyces without number. As a rule, very few flowers will have split calyces provided the treatment is correct, the newer varieties being particularly notable for their strong calyces.

Some growers keep young Malmaisons through the winter in small pots; others give them a shift in autumn. The best period for this operation is from the middle to the end of September; and it may be noted here that drainage composed of very small bits of potsherd gives better results than moderately large nodules. The shift should not be large at this time, and if the compost is very firmly pressed into the pots, little water will be needed till about the end of January, that is, of course, provided the plants are wintered in a cool and dry structure. Though the plants do not appear to progress much, if at all, they are really building up a stout, thick stem, with abundance of roots slowly ramifying in the soil, and when spring comes they are in the very best condition

to leap into vigorous growth. A watch should be kept for the appearance of green fly, a pinch or a puff of tobacco powder, if caught in time, being sufficient to keep it under.

This is the proper time, too, to plant out border varieties. It must be remembered that the earlier they are planted, once well rooted, the better will they be established when winter comes, and consequently less liable to suffer from the vicissitudes of the weather. Wet or damp is the only thing inimical to the border Carnation. It is accordingly a good plan not to plant deeply. Keep the stem up, and, if a strong plant, support it with a short stick, rather than set it deeper and risk disease. In

THE MEADOW SAFFRON (COLCHICUM SPECIOSUM).

soil naturally conservative of moisture, the beds should be slightly rounded instead of flat, and lime in some form laid over the surface will be of value. Plants to be potted up should not be delayed either, having regard to the habit of the variety and seeing that strong-growing kinds shall have ample root room and the less vigorous ones not so much. I make it a practice, when new varieties are introduced at this time of year, to invariably grow these in pots. No matter how careful the vendor may be in lifting and packing, the layers receive a check, which is overcome with no loss when they are placed in pots, but this can hardly be expected if planted out.

R. P. BROTHERSTON.

THE MEADOW SAFFRON.

COLCHICUM SPECIOSUM is, without exception, the finest of all the coloured forms of this pretty and acceptable group of hardy autumn bulbous flowers. It is, indeed, like the noble Emperor

Daffodil among its fellows, calculated to excite the admiration of anyone, and in particular those making the acquaintance of it for the first time. Like the Daffodil just named, the Meadow Saffron is also the possessor of a bold

and vigorous constitution that fits it for a great variety of soils and aspects. Not that the latter will bear comparison with the Daffodil in the matter of multiplication, yet with care and discreet management a good stock may soon be obtained, and certainly no others of the genus are more worthy of all this care.

As for soils and the position most likely to suit the plant, and encourage also that rapid increase

to which I have briefly referred, I have found the following the most suitable: A bed of rather holding loam, with one-fourth of good half-decayed leaves and the same proportion of year old cow-manure. By adding good sharp grit or charcoal dust to the same extent, one has an excellent compost.

It is a curious fact that rare or choice things are usually given a mixture with a percentage of peat as likely to be the most useful. I have, however, never observed any benefit from doing so. In light soil, with the better kinds I have used cow-manure freely, and in this way: Digging out 6 inches of the soil and running the manure, on to the bed, to be deeply dug in below the corms, then levelling up the soil, and finally planting 4 inches deep. In this way and in a light, almost always workable soil the Colchicums thrive remarkably well, and give leafage that also is a guarantee of their success. I prefer to employ manure thus deeply turned in because of its cooling nature, and also because the leafage of these Meadow Saffrons, coming in spring-time, shall not suffer or be brought too quickly to an end by the first heat of the year. Given a deep and cool rooting medium, and, if possible, a partially shaded spot, their progress will be sure to give satisfaction. Of course, these Meadow Saffrons may be grown in

quite ordinary soil in the shrubbery, the border, and similar places, but the better kinds of Colchicum amply repay greater care in their cultivation. To increase them, lift every third season and divide and replant as soon as the foliage is fully matured. These plants are not benefited by a long season out of the ground; rather do they lose vigour when this is continued for any length of time. It should be stated that the example in the illustration is greatly reduced in size, and that the plant when well grown is fully 9 inches high. The handsome purplish rose flowers are strong and deep supporting. The typical species comes from the Caucasus, but there is also a pure white form in cultivation.

J. E.

BULBS FOR GRASS AND WOODLAND.

IN the early days of spring, when we have tired of looking upon broad expanses of seared greensward and beds of naked shrubs, we welcome with more than usual warmth those bright little heralds of spring, the so-called Winter Aconites, each of which has its golden, Buttercup-like flower set in a frilled collar of greenery that always reminds us of the ruffs of the Elizabethan period.

since Kew gave the lead some years ago, and where planting has been done with proper regard to effect and suitability or otherwise of the position selected for the various kinds, the result has invariably proved satisfactory. A word of warning is necessary to those who would plant bulbs in grass. This must not be cut until the foliage of the bulbs takes on a rusty or yellow appearance.

The Winter Aconite has already been mentioned, and where a sheet of yellow is desired in the month of January, this should be planted in quantity at once. It will thrive in grass, or in cultivated spots in the shrubbery, and, once established,

is *G. Elwesii*. A charming effect can be obtained by planting Snowdrops and the beautiful little blue Squills, *Scilla sibirica* and *S. bifolia*, together.

Mention of the Squills reminds one of that charming little denizen of the Alps so aptly named Glory of the Snow, but known to botanists as *Chionodoxa Luciliae*. This is brilliant blue, each flower having a white centre. It is suitable either for planting in grass or the shrubbery, and many use it as an effective carpet for beds of shrubs. A somewhat rarer and even richer-coloured kind is *C. sardensis*, its blossoms having that intense blue colour that we find in the Gentians.

DAFFODILS NATURALISED UNDER TREES. BULBS SHOULD BE PLANTED NOW.

Following closely on these Aconites, and sometimes keeping them company, come the Snowdrops, and from then onwards until the Wood Hyacinths have finished their display, and the virgin beauty of the Beech foliage has departed, the woodland and shrubberies may be kept bright and interesting with bulbous plants alone.

As planting-time is with us, there is good reason for drawing attention to the lesser-known bulb best suited for growing in grass, under the shade of large trees, for shrubberies and large beds of deciduous shrubs such as the Lilacs. The system of naturalising bulbs in such positions as those mentioned above has been widely adopted

seeds and perpetuates itself freely. Snowdrops are rather more difficult to accommodate, and if grown in grass, where they look exceedingly pretty, and where their flowers do not get soiled so easily, it may be, and often is, necessary to plant a few fresh bulbs each year, otherwise, and particularly on sandy soils, they will most likely die out in the course of a few years. Cool, loamy soil in the shrubbery or large beds is an ideal spot for them. If the soil is of a sandy character, plant the bulbs at least 6 inches deep. For naturalising, the common Snowdrop, *Galanthus nivalis*, is best; but a larger-flowered variety that may be used for more favourable positions

At present it is rather expensive for naturalising, but it might well be utilised in moderate quantities for large beds. For the same purpose the large-flowered *C. gigantea*, or *grandiflora* as it is sometimes called, is most effective. The flowers of this are twice the size of those of the well-known Glory of the Snow, pale lavender blue in colour, and the habit of the plant more robust.

From the *Chionodoxas* it is but a short step to the Anemones or Windflowers, among which we find several eminently suited for our purpose. One of the most beautiful of these is the Mountain Windflower, *A. apennina*, a dainty little plant some 6 inches high that transforms the place

wherein it dwells into a dense, waving mass of starlike, sky blue blossoms. Similar in form, and rather deeper in colour, is the Grecian Windflower, *A. blanda*. It flowers several weeks in advance of *A. apennina*. Of our native Wood Anemone, *A. nemorosa*, there are several excellent forms, the most charming of all being *robinsoniana*. This has large single flowers of pale lavender colour, and should be planted in large drifts. *Allenii* and Blue Bonnet, both having blue flowers, and *bracteata flore pleno*, or Jack-in-the-Green as it is often called, a double white variety, may all be planted freely. These Windflowers delight

For planting among hardy Ferns, where these are grown under tall trees, the dainty little hardy Cyclamens, which blossom in spring, are available, and their small but curiously shaped flowers form a pleasing contrast to the russety brown foliage of the Ferns, which all good gardeners allow to remain until new fronds are seen in spring. Two that may be planted freely are *C. Coum* and *C. ibericum*. There is little difference in the flowers, but the foliage varies, the former having plain green leaves and the latter a silver zone to each leaf. Of *ibericum* there are varying shades of colour, ranging from a white flower

with a crimson eye to blossoms of rich crimson. The Ivy-leaved Cyclamen, though it flowers in autumn before the foliage appears, is of interest in the spring, as its tufts of leaves are marbled with charming silvery tracings. The roots of these Cyclamen should be planted about two inches deep, and a fair proportion of leaf-soil ought to be present in the ground in which they are planted.

An article on bulbs for the woodland would not be complete without mention of the Muscaris or Grape Hyacinths, the prettiest of all being Heavenly Blue. At Daffodil-time this will transform banks or shrubbery into a veritable cloud of sky blue. Plant freely and in large colonies, as a bold effect is desirable. Other good Muscaris are *comosum* and *plumosum*. A charming little flower that one seldom meets

is *Puschkinia libanotica*, or the Lebanon Squill. It grows about six inches high and forms clusters of dainty flowers, which are, perhaps, scarcely bright enough for bold effects, but which are, nevertheless, beautiful in the front part of the shrubbery, where they can be seen at close range. The blossoms are semi-transparent and white, each segment being striped with blue, resembling a piece of old china. *Allium Moly* and *A. neapolitanum*, with yellow and white flowers respectively, and the Snake's-head Fritillary (*Fritillaria Meleagris*), a native plant suitable for a damp, grassy situation, must complete our list for the present, though many more might be added. Daffodils have been purposely omitted, as their merits and requirements are now well known. In planting bulbs for natural or bold effects, anything approaching formality of arrangement must be strictly avoided. In grass a large colony of one kind should be planted, and a few odd plants may well lead us on, as it were, to another cluster of good dimensions.

BULB PLANTING AND TRIAL GARDENS.

BY THE REV. JOSEPH JACOB.

SPEAKING in a general way, there are three parts of an ordinary garden in which bulbs may be planted: (1) the mixed border, (2) the parterre, where there is a collection of formal beds arranged in a more or less complicated design, and (3) the larger or smaller isolated beds which more often than not are cut out of grass.

Although it is the custom to write of bedding arrangements in the autumn, it must be very tantalising reading for many; for the greater the success of the writer in describing effective combinations and displays, the more he is able to make people's mouths water by putting the delights of a well-considered garden before them, the greater the aggravation to feel that all these joys are impossible without the previous preparation of the necessary little plants which under modern taste are an inseparable adjunct of the bulbs; or without a very serious expenditure upon young seedlings or newly struck cuttings. The purchase of Arabis, Aubrietias and *Cerastium tomentosum*, to name three of the most usual and useful of the plants employed, would be a large item where there is any considerable space or number of beds to fill.

On the principle of look before you leap, it seems to me that I might be doing a very useful thing if I were to suggest the formation of a *trial garden* where two or three of all sorts and conditions of hardy bulbs, annuals and perennials might be gathered together for reference and study. I have recently been reading a newly published book by Mrs. Frances King of Michigan, U.S.A. called "The Well-considered Garden." It is a pæan on the joys of harmonious colour blending in gardens, and although it is, naturally, written from an American standpoint, there is one chapter which insists upon a practice which in its far-reaching usefulness is most truly catholic; for is not such an adjunct of use, as Vincentius wrote, everywhere, at all times and for all people?

A deliberately planned trial garden is a rare thing to find. Yet if one wishes to ensure a harmonious blending of the occupants of our beds and borders, no suggestion can be more practical. There under our own eyes we will see samples of everything that seeks for admission, and we can note its shade or tone of colour and how it would look were this or that its bed-fellow; and what is of equal importance, we can test their relative times of opening, this last observation being perhaps of more particular utility with regard to spring arrangements and formal bedding. These are the questions which the trial garden will answer: Will there be sufficient of the foliage of *Funkia sieboldiana* above ground to act as a carpet to some deep crimson Darwin Tulip like Millet? Will a pale blue Forget-me-not like Queen Victoria or a rich dark one like Indigo Queen or Sutton's Royal Blue, set off the orange brick red of Tulip Prince of Austria? Which of the pale Aubrietias, like Bridesmaid or Lavender, will act as the best foil to a dark Tulip like Viking? Is there any difference in the time of blooming between *Chionodoxas Luciliae*, Boissieri and *Tmolusii*? How does *Agapanthus umbellatus* do if left out all the winter? The questions that might be asked are more in number than the sands of the seashore. Every gardener, according to his knowledge and inclinations, will have different

INTERIOR OF MESSRS. GEORGE BUNYARD'S FRUIT ROOM.

in a shady position, and thrive well under large trees, especially where the soil receives some slight cultural attention.

The ordinary florist's Crocuses in yellow, white and varying shades of blue are frequently used for planting in grass, but there are two lesser-known kinds with more refined flowers. One that opens its flowers early is *C. susianus*, or Cloth of Gold as it is known to some. When the flower-buds appear, and before they open, their colour is a rich glossy brown; but when the petals fall back and reveal the golden interior, the plants do, indeed, form a carpet of gold. This Crocus may be planted freely in grass or in the shrubbery. Flowering at nearly the same time, but in some localities rather later, we have in *tommasinianus* a Crocus of more than ordinary beauty and a plant for naturalising in the grass. The flowers are clear lavender blue, with a silvery sheen on the exterior, the beautiful orange stigma in the centre adding not a little to its charm.

ones to submit. The trial garden will answer them all.

All the time that the old stock favourites are being used in the parterre or in the isolated beds on our lawns, we can in this testing station be preparing fresh surprises for our friends and new and greater pleasures for ourselves.

The time to establish such a garden is the autumn. Its size will be determined by the work that will be given it to do and the class of vegetation with which it will be filled. For testing blending, timing and doing it is, and always must be, invaluable. How is it, then, that we so seldom find one even in our large establishments?

It may be because such an idea has never occurred to the owners or managers; it may be because they have never realised its possibilities or the deep interest which it is bound to create; it may be that journal writings and catalogue descriptions are too slavishly relied upon.

But have these never failed you? Have you never had surprising jars of colour when you have gone entirely by a list? Or, when you have seen the self-same arrangement for the fourth or fifth time, has not the idea of a change ever occurred? Has not "let well alone" sometimes palled upon you? Try, then, a trial garden. Here failures instruct and lessons enthuse.

FRUIT ROOMS.

NEXT to careful growing and development of fruit is the preservation of it for use over a long period. For this purpose no better form of fruit room can be desired than the one we now illustrate, which is inexpensive, and yet answers so well that Messrs. Bunyard's exhibits of late-kept fruit at the Chelsea Show have become a feature of that meeting.

The main points are to use the natural earth for the floor, in order to keep it just damp; when this is secured, the timber used does not cause the fruit to shrivel. Pears are kept from July to April, and Apples from July to June. Cut flowers, &c., can be kept fresh in the summer in the house, but no Potatoes or Onions should be stored in it, as they are apt to flavour the fruit. Large fruit is laid in single layers; the smaller dessert fruit can be three or four deep, as late sorts keep sounder in this way.

The fruit house illustrated is at the Langley Nursery, near Slough, and was used for many years by the late firm of Messrs. J. Veitch and Sons. It is about 35 feet long, 13 feet wide, 6 feet high to eaves, and 10 feet to ridge (inside measurements); the sides and roof are thatched with straw, with heather on the outside, and are about 1 foot to 18 inches thick. It is provided with padded shutters to the windows and ventilators, and an outside door of the same material about 5 inches thick, as non-conductors to heat and cold. It is entered by double doors, over which and at the opposite end are windows with ventilators, all of which have also shutters on the inside to control the light and air. The whole of the inside is lined with match-boarding. There are four tiers of stages around the sides, 2 feet 6 inches wide and 1 foot 6 inches apart, formed of battens similar to a greenhouse stage. In the centre is an exhibition table 3 feet high and 3 feet wide. The paths are 2 feet 6 inches wide. The whole of the interior lining and stages is of white deal.

ROSES IN YORKSHIRE.

ONE of the problems confronting amateurs with limited means, and yet with some claims to artistic taste and sense of colour, is the difficulty of adding various new Roses and yet preserving that balance of colour, blending of tones and shades, that ultimately make or mar the general effect of the whole garden, be it large or small. This is always my own problem when I pay that annual visit to the nursery and see long rows of one variety after another, well aware that I cannot plant six each of all the newest and best. However, success is all the sweeter after having made and subsequently remedied mistakes of this sort. One of the varieties that seems to ask for a bed to itself is

Lyon, for either in the garden or vase its rich tones of salmon pink and lobster red seem to defy competition, and cause other fine colours to appear at a disadvantage. One or two varieties, however, I find may be planted in conjunction with Lyon, with pleasing results. One of these is

Lady Pirrie, a deep coppery salmon with a suspicion of fawn, a delightful combination of colour. This variety has proved a very free and abundant bloomer here.

Mrs. Alfred Tate, the colour of which is very similar to Lady Pirrie, but coppery red rather than salmon tone, is also an excellent bedding Rose, with the form and habit of Betty, and is invaluable for table decoration. It is a great pleasure to see such a dainty type of Rose

few Roses with many petals that opened well throughout the very showery July and August.

Mrs. Herbert Hawksworth, ivory white, with large, globular flowers, was continuously in bloom. This is undoubtedly one of the very best of the whites or creams. Its habit of growth is very vigorous and of great value here in Yorkshire, where comparatively few white Roses repay the grower. Second only to this is

Mrs. Herbert Stevens, another white of very graceful growth and a prolific bloomer, giving us quantities of long, pointed blooms of perfect shape. Moreover, it blooms in spite of rain.

Mabel Drew is another successful Rose. Its colour is deep cream, and has large, full and well-formed flowers of refined shape. It blooms with me as freely as Mrs. David McKee, and is a welcome acquisition to the garden.

Lady Greenall.—Here is a Rose that worthily upholds the reputation of "Newtownards." The colour is pale buff, opening to deep yellow; very large and handsome flowers, held on long, erect stems; the foliage is an attractive bronze, and with me free from mildew.

Lady Downe.—This variety I planted last autumn on the recommendation of a friend, and it has fully justified its place in the garden. The colour is a deep buff, passing to a still deeper yellow, which, however, pales off very much in the fully opened blooms. It is very fragrant and also appears mildew-proof. It reminds one very much of Mme. Ravary, a variety which it rivals in its freedom of growth. Another charming little Rose that must be mentioned here is

Mrs. Peter Blair, a pure lemon yellow, producing quantities of perfect-shaped flowers in great

THE FRUIT HOUSE AT THE LANGLEY NURSERY, NEAR SLOUGH.

succeeding in this strenuous climate. Yet another Rose of the Lyon type is

Willowmere, a lovely deep peach pink, a sturdy and erect grower that has produced perfect blooms here in abundance. This, in my opinion, is a Rose that will become very popular when better known.

Mrs. Amy Hammond.—This is a Rose that pleases me very much. Its colour is a very pale creamy salmon, but with such large and finely built blooms and delicate scent. It is one of the

profusion. It is evidently a very hardy variety, and for that reason alone is worthy of note by growers who have a cold and exposed situation to contend with.

Mrs. Frank Bray.—This is considered by some growers to be an improvement upon Mme. Ravary (an opinion I do not share), yet it is a most excellent Rose, a deep coppery écu with the faintest suspicion of shell pink, and worth growing for the beautiful buds. A fine buttonhole variety.

Roundhay.

E. WATERS

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Strawberries in Pots.—During times of hot, dry weather the plants will need close attention to watering. Stimulants also must be more frequently afforded now that the pots are full of roots. Soot-water is an excellent stimulant for the Strawberry, and may be given at least once a week. If the plants are too crowded, they should be thinned out, for it is essential that they get all the sunshine and air possible in order to thoroughly ripen the crowns. A spraying once a week with a mildew specific will keep the foliage free from this pest.

Early Pot Vines.—The Vines which have been grown for supplying fruit early next May should now be thoroughly matured. About the beginning of next month they may be shortened to the desired length. They may then be placed in an exposed position outdoors till the beginning of November, when they must be placed in the forcing-house. The Vines which are likely to give the best results are those of medium strength and with short-jointed growths.

Early Permanent Vines.—The Vines which are to be started into growth early in November should be ready for pruning the first week in October. Old-established Vines give the best results for very early forcing. It is not prudent to prune very old Vines back too hard; in all cases three or four good buds should be left after pruning. Where there is room to lay in young growths, this should be done, as it is from such that the best bunches will be obtained. The Vines should be subjected to a thorough cleaning. If mealy bug is troublesome, all the loose bark must be removed before scrubbing the rods with a strong insecticide. The house must also be well washed and the walls limewashed. The borders must then be relieved of 2 inches or 3 inches of the surface soil, replacing this with fresh materials.

Plants Under Glass.

Violets.—The plants must now be placed in their winter quarters. A shallow pit is the most suitable structure in which to grow Violets in the winter. Chopped loam and naturally decayed Oak or Beech leaves make an excellent compost. The materials must be elevated quite near to the glass, as the plants require all the light possible. Before planting, dip the foliage in an insecticide as a precaution against red spider. Plant firmly and thoroughly soak the materials when finished. Keep the frames close for a few days till the roots are again active, then gradually inure the plants to cooler conditions, eventually removing the lights altogether, except when sharp frost is imminent.

Tree Carnations.—These plants must now be given a mean temperature of 50° or 55°. The earliest batch will now be in need of a little stimulant, but this must not be overdone. Syringe between the plants on fine days, but do not drench the foliage. If cuttings are available, a batch may be struck now.

Spiræa.—Retarded roots of this useful plant may now be started into growth. A moderate temperature is necessary till growth is well advanced. They may then be placed in a warm, moist atmosphere. These plants need abundance of water at the roots.

Coleuses.—Where these are grown from cuttings, no time must now be lost in getting these rooted. Insert the shoots around the sides of small pots and place them in the propagating-case. They must be examined every morning, removing dead leaves, or many of the cuttings will be lost through damping.

The Flower Garden.

Anchusa italica.—To keep a true stock of this beautiful Borage, the old plants should be lifted every two years, retaining the most promising roots for replanting. It is wise to pot up some of the pieces and winter them in a cold frame, planting them out in the spring. The plants left out in the border must be protected by placing ashes around them.

Dahlias.—Beds of these beautiful flowers are often spoilt by early frost. Where practicable, the beds should be protected with tiffany or something similar. See that the plants are well supported

with strong stakes as a precaution against autumnal gales.

Heucheras.—These useful plants may be increased by inserting cuttings, which are now plentiful. A batch should be struck every year, as old plants do not flower so freely as young ones. The cuttings will readily root in boxes of sandy soil. Keep them close in a cold frame till they are rooted, then gradually harden them off. They may be wintered in frames and planted out in the spring.

The Rock Garden.

Bulbs.—Many of these may now be planted in the rock garden. The smaller-growing Narcissi, Muscari, Chionodoxa and Scillas, may all be grown in small rock gardens. In bold schemes of rock gardening many of the May-flowering Tulips may be planted. The beautiful *Habranthus pratensis* may be planted in sheltered nooks; but it must be exposed to full sunshine. Anemones must be planted freely among the rocks. *A. apennina*, *A. blanda* and *A. alpina* are very showy subjects for the rock garden.

The Kitchen Garden.

Late Peas.—A good watering with diluted drainings from the farmyard will considerably enhance the filling of the pods. Tits are often very destructive among late Peas, but they may easily be prevented by covering the rows with fish netting.

Carrots.—The main crop of Carrots must now be lifted. The roots should be carefully lifted with a fork, and, after they have been carefully selected, the best may be placed in their winter quarters, leaving those which are blemished for immediate use.

French Beans.—A sowing of a good forcing variety, such as Osborne's Forcing or The Belfast, may be made now in pots. Place the pots in a warm, moist house, and when the Beans are through the soil keep them near to the light and syringe them twice daily.

Beet.—If this valuable crop has not already been taken up, no time must be lost in doing so. Take up the roots with great care, as the least damage will spoil them. They may be stored in sand in a cool shed. E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Flower Garden.

Border Carnations.—In wet districts the layers are much better lifted and either potted or planted fairly closely together in cold frames, where they should remain until March, giving plenty of fresh air at all times, except during hard frost. This work should now be attended to. After potting or planting, very little water will be required, and, as it encourages rust, care should be taken that it does not touch any part of the foliage.

Roses.—Where Roses are required to be grown on their own roots (and this has its advantages in many cases), cuttings should now be put in sandy soil in frames. Some varieties, such as Dorothy Perkins, root very readily, while others are more difficult to strike. In all cases it is best to get cuttings with a heel attached, choosing medium-sized growths which are fairly firm or ripe.

Spring Bedding.—As most of the summer-flowering plants are becoming very untidy, they had better be removed without further delay, even if they have not been actually cut down by frost. The spring-flowering plants can then be put in their permanent quarters before the more severe weather arrives, which very often prevents this work being carried out expeditiously.

Rock Garden.—Many subjects having a herbaceous habit are quite ripe and ready to be cut over. This should be done and a general overhaul given to maintain a tidy appearance. Bulbs which are to be planted in this garden should be got in as soon as procured.

Zonal Pelargoniums are now liable to be injured by frost, so if any cuttings are not yet

under glass, they will be safer if removed without delay. Keep in houses where there is an abundance of ventilation.

The Kitchen Garden.

Cauliflower.—There is usually a glut of this vegetable at this season, and also a danger of its being injured by an early frost. In view of this, any which are ready for use and cannot be consumed could be lifted and hung up in a damp cellar or shed until required. Any plants inclined to be late in forming heads might be lifted into a cold frame if there is space available.

Runner Beans.—As long as frost does not injure the plants, the pods should be kept closely picked off as soon as they are large enough to use. This tends to encourage the production of more young pods.

Peas.—The crops obtained from late sowings depend very much now upon the weather for the next few weeks. Should the ground be at all dry, a watering had better be given, to which some stimulant has been added. Any exhausted crops remaining on the ground should be cleared up and burnt on the spot, after the Pea stakes have been gathered and put in store ready for use another year.

Lettuce.—During a very wet period these are liable to be spoilt through many of the leaves damping. Where portable frames are available, these should be placed over them, and the lights kept tilted to admit all air possible.

Fruit Under Glass.

Pot Fruit Trees.—Before the leaves fall is the best time to repot and generally overhaul the trees. The small trees in 10-inch to 12-inch pots must be repotted annually. Larger ones do not require disturbance for several seasons if the drainage is kept in order and a top-dressing given to keep the surface roots active. The soil used must be good fibrous loam, well enriched with artificial manure of a lasting nature. To this should be added a good proportion of lime refuse and charcoal to keep the soil open and sweet.

Peaches and Nectarines growing in borders which are unsatisfactory should be attended to as soon as the wood is sufficiently ripened, as it is much better to transplant before the foliage drops. Before commencing, the trees should be shaded if the weather is at all bright. If the drainage is at fault, this must be put right before replacing any of the soil. Add plenty of lime refuse when making up the border, as this is a very important ingredient where any stone fruit is concerned. All through the operation, when the roots are exposed, keep them well moistened with the syringe and also covered with mats.

Plants Under Glass.

Amaryllis plants should now be sufficiently ripened off, so further watering will not be necessary; in fact, it would be harmful. Remove them to a sunny shelf in some cool house where there is plenty of ventilation. Later, place them under some plant-house stage, laying the pots on their sides to prevent any danger from moisture dripping on them. It is well to examine the plants for mealy-bug, as this is sometimes troublesome when it finds a hiding-place under the scales of the bulbs.

Liliums.—Both *L. auratum* and *L. lancifolium* varieties will be worth keeping for another season if the plants have not been forced in any way. The pots containing the bulbs should be stood outdoors in a sunny position until the growths have completed ripening. When this has taken place, the pots should be removed indoors and laid on their sides, eventually shaking the bulbs out and repotting for next season's display.

Housing Tender Plants.—Many subjects which may grow well in cold frames during the summer months quickly show the ill-effects through receiving a check owing to a low temperature, which is always possible at this time. Cyclamen, Cinerarias, Primulas and Pelargoniums, among others, should therefore be removed to houses and pits where artificial heat can be used either during cold or very damp weather. The latter is equally as harmful as frost, so that a gentle warmth should be kept in the pipes, sufficient to dispel an over-abundance of atmospheric moisture.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Cattleya Venus Princess Mary (C. Iris × C. aurea).—A very handsome hybrid; sepals and petals bronzy yellow, lip crimson purple. The plant bore a two-flowered scape and was a great attraction. Shown by Messrs. Charlesworth and Co., Hayward's Heath.

AWARDS OF MERIT.

Dendrobium hookerianum Fowler's Variety. The pseudo-bulbs of this variety were 2½ feet high; the flowers, which are borne near the summit, are coloured rich golden, with heavily fringed lip, and marked with a big blotch of maroon at the base.

Cattleya amabilis Fowler's Variety (C. labiata × C. Warscewiczii).—The sepals and petals are rose coloured, lip crimson purple. A very handsome variety. These two were exhibited by Mr. J. Gurney Fowler, Pembury, Kent.

Polypodium Dryopteris plumosum.—The varietal name is descriptive of a very charming and beautiful form of the well-known Oak Fern, which, we believe, has not hitherto shown any tendency to sport. The above, however, will be welcomed by all lovers of the Fern tribe, as, independently of its plumose character, it is decidedly taller and more vigorous. It is both an addition and acquisition. From Mr. T. G. H. Elley, Burgess Hill, Sussex.

Ceanothus Fantaisie.—A very beautiful and distinct variety with erect pyramids of rosy lilac flowers. It is said to be very freely flowered and excellent for bedding. Height, 2½ feet or thereabouts. Sent by Elizabeth Lady Lawrence, Dorking (gardener, Mr. W. Bain).

Strawberry St. Fiacre.—An autumn-fruiting variety of good size, which, if of good flavour, will meet with a great welcome. The fruits are light scarlet in colour. From Messrs. Bunyard and Co., Maidstone.

The foregoing novelties were exhibited before the Royal Horticultural Society, at Vincent Square, Westminster, S.W., on September 14, when the awards were made.

NEW DAHLIAS.

Vanesse (Pompon).—Pure white, of quite model form and great purity.

Cresset (Collarette).—Maroon guard florets, white collar.

Curlew (Cactus).—Good form, coloured rosy mauve.

Esmee (Cactus).—Clear pale yellow self.

Constance (Cactus).—Clear rose pink, distinct and good.

Coyness (Cactus).—Pink, white centre. These were shown by Messrs. Burrell and Co., Cambridge.

Sappho (Decorative Single).—A handsome and distinct sort. Coloured buff and edged white.

Don Juan (Collarette).—Of crimson and yellow colour.

Tipperary (Single).—Crimson with white tips. These were shown by Mr. Reginald Cory, Duffryn, South Wales.

Blaze (Decorative).—A richly coloured variety, as the name suggests. From Messrs. Carter and Co., Raynes Park.

THE NEW DECORATIVE SINGLE DAHLIA SAPPHO.

Gossamer (Cactus).—The colour is orange yellow.

A. R. Perry (Cactus).—Ruby red and tipped golden.

Sharmon Crescent (Cactus).—Pale primrose and pink. These were from Messrs. J. Stredwick and Son, St. Leonards.

William Pound (Pompon).—A model flower of primrose yellow colour. Shown by Mr. S. H. Cooper, Chippenham.

The above-named Dahlias were adjudicated upon by a joint committee of the Royal Horticultural Society and the National Dahlia Society, and carry the award of merit of the former and first-class certificate of the latter. The large decorative single novelties were particularly striking.

NEW ROSES.

THERE were some very beautiful novelties placed before the New Seedling Committee of the National Rose Society on September 16.

GOLD MEDALS.

Modesty.—A delightful Hybrid Tea of great depth of blossom and perfect form. This must become a grand exhibition variety, as well as a good garden Rose. (See illustration, page 467.) It is somewhat on the lines of Countess Clanwilliam in tinting, but a more creamy shade, and a mixture of fawn and pink. It possesses huge winged outer petals that add much to the beauty of the very elongated centres.

Golden Emblem.—At first sight we thought an extra fine basket of Rayon d'Or was on view, but on closer inspection we found a fuller flower and more superb buds, with the intense Maréchal Niel yellow so much admired and so difficult to produce in Roses of quality. We have hopes that in the near future there will be evolved a truly dwarf Maréchal Niel, for, however much we admire these Pernetiana Roses, they leave something to be desired in a fuller and more elongated centre. The growth of Golden Emblem is splendid. Both of these gold medal varieties were shown by Messrs. S. McGredy and Son.

CERTIFICATES OF MERIT.

Tipperary.—A Hybrid Tea Rose of a colour that reminded us of Melody, with just a shading of the glorious golden yellow of Lady Hillingdon, and the form more like Souvenir de G. Prat. Shown by Messrs. S. McGredy and Son.

Ulster Volunteer.—A grand single Hybrid Tea, something like a glorified Sheilagh Wilson, but with more bushy habit and really perpetual. The flowers shown were immense, and the two year old plant was a marvel of vigorous bushiness, giving one some idea of its decorative value. Shown by Messrs. Hugh Dickson, Limited.

National Emblem.—A very rich velvety crimson Hybrid Tea, open flowers, reminiscent of our old friend Charles Lefebvre. It is a little weak in the shortness of the centre petals, but it is a very fine kind, and will be planted largely until a better one comes along. Raisers seem to be a long time giving us a good crimson Hybrid Tea with the Hybrid Perpetual form. An Alfred Colomb with the colour and freedom of National Emblem would be great. Mr. McGredy informed the writer that he has a seedling of the form and colour of Prince C. de Rohan, only double its size, such a seedling would be welcomed by all rosarians, and one becomes impatient to possess such a beauty. Shown by Messrs. S. McGredy and Son.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

ASTERS FAILING (H. B. Brooking).—The Asters are attacked by a "damping off" fungus, which has recently been shown to be a species of *Phytophthora*. This fungus enters the plant from the soil and does considerable damage to Asters. It would be well another season to sow seed only in soil which has been steamed, in order to kill the spores which are likely to be in it, and to plant the Asters on a fresh site.

DAFFODILS IN WOODLAND (A. W. Rydon).—We cannot hold out much hope of success for planting these in a woodland walk where the ground is rather hard, and the first essential is that it should be broken up sufficiently to give the bulbs a fair chance. The *Poeticus Narcissus* also prefers moisture and a cool rooting medium. All woodland planting should be naturally done, and not a bad way is to strew the bulbs thinly broadcast and plant them where they fall in as informally a manner as possible. Avoid continuous planting; a break is at once a change and a rest. Small slopes should appear as though the bulbs had seeded down the bank. Field-mice rarely touch Daffodils, but are fond of Crocuses and other bulbs. Snowdrops and *Chionodoxa* should not be too near tree trunks, and the same rules of planting apply to all. A thousand would not make a very big show, but it would at least constitute a beginning.

ROSE GARDEN.

ROSE CHATEAU DE CLOS VOUGEOT SPORTING (G. Smith).—We have not seen this Rose sport a pink flower, but most varieties sport at some time during their career.

ROSA RUGOSA AS HEDGE (Y. E. R. P.).—*Rosa rugosa* can be used for a hedge of an informal character. Plants can be inserted about 1½ feet apart, and they will form a good hedge in the course of two years. They may be pruned fairly hard in March, but little pruning is advisable at other times. The type is the best kind for the purpose, but the hybrids *Conrad F. Meyer* and *Blanc Double de Coubert* can also be used, particularly the last named.

TWENTY-FOUR GARDEN ROSES OF FREE GROWTH AND FREE BLOOMING HABIT (J. Gibson).—Omitting the varieties you name, we can highly recommend the following: *Hugh Dickson*, *Ophelia*, *Lady Ashtown*, *Mme. Second Weber*, *Mme. Leon Pain*, *G. Nabonnand*, *Mme. A. Chatenay*, *Mme. A. Mari*, *Prince de Bulgarie*, *Amateur Teysier*, *G. Grunerwald*, *Joseph Hill*, *Mrs. H. Brocraebank*, *Lady Hillingdon*, *Duchess of Wellington*, *Molly S. Crawford*, *Lady A. Stanley*, *Lieutenant Chaux*, *Mrs. H. Stevens*, *Mrs. E. Powell*, *Countess of Shaftesbury*, *Cissie Easlea*, *Mme. E. Herriot* and *Louise C. Breslau*.

THE GREENHOUSE.

CYCLAMEN EATEN (Mrs. H. C.).—The little creatures devouring the roots of your Cyclamen are not slugs, as you suppose, but the grubs of a beetle with totally different habits and life-history. It is a weevil, a species of *Otiorynchus*, which, when mature, feeds on the foliage of various greenhouse plants. It lays its eggs in the soil, and the larvæ often feed on a variety of plants under glass, but sometimes in the open. Your best plan will be to turn the plants out of their pots and pick the weevils out, though pouring a small quantity of carbon bisulphide into a hole made in the soil, so long as it does not touch the roots themselves, would probably kill the larvæ.

KITCHEN GARDEN.

CELERY LEAVES DISEASED (M. R. P.).—The Celery leaves are attacked by the Celery leaf-spot fungus, *Septoria petroselinii* var. *Apii*. This fungus has been very prevalent during most seasons recently, and is likely to be this, as it is so wet. It is carried from place to place by the seed, and is best kept in check by spraying with Bordeaux mixture. This spraying should be commenced in May, and it is

probably too late to do much for your plants now, but if you have any free from the trouble it would be well to spray them; indeed, it would be a wise precaution for everyone to take at the present time, if they would keep their plants free from the disease, even though they have seen nothing of the trouble so far.

FRUIT GARDEN.

APPLE SHOOTS WITHERING (P. O'Brien).—The damage to the trees is due to cold winds or some similar cause which reduces their vitality.

PEAR LEAVES DISEASED (Bo-is).—The Pear foliage is attacked by the Pear leaf-blister mite, which winters between the bud scales. It is important to deal with it in winter by spraying with the Oregon wash, a recipe for which has been given in our "Answers to Correspondents" columns frequently.

MISCELLANEOUS.

BOOK ON BULB FORCING (H. M.).—We regret that we do not know of any book dealing fully with the forcing of bulbs for the Christmas trade.

INSECT FOR IDENTIFICATION (J. H. H. Cardiff).—The creature sent is either the Australian or the American cockroach, but arrived too much battered to enable us to be sure. We have found the "V.T.H." Slug Trap excellent for catching these pests; or one may use poisoned bait of the kinds frequently advertised in our columns, or beer put at the bottom of a smooth-sided vessel with a piece of wood leaning against it to form a bridge for the insects.

NAMES OF PLANTS.—*Mrs. Fawkes*.—*Juncus supinus*.—*H. C. R.*—1, *Veronica spicata*; 2, *V. longifolia*; 3, *Eriogon macranthus* variety; 4, *In patiens Roylei*; 5, *Polygonum cuspidatum*; 6, *Thalictrum minus* variety. —*Miss C. C. Innerleithen*.—*Rose Burgmeister Christen*, *Clematis integrifolia Durandii*, *Lathyrus 1-tifolius albus* Queen of the West, and *Bupththalmum salicifolium*. —*F. C. B., County Antrim*.—*Solanum nigrum* variety: looks like the Wonderberry.

NAMES OF FRUIT.—*E. A., Copmanthorpe*.—1, Worcester Pearmain; 2, Cox's Pomona; 3, Duchess of Oldenburg; 4, Stirling Castle; 5, Ecklinville; 6, Cox's Orange Pippin; 7, Lord Suffield; 8, Alfriston; 9, Lane's Prince Albert.

SOCIETIES.

NATIONAL ROSE SOCIETY'S SHOW.

FROM every point of view the society's autumn exhibition held at the Royal Horticultural Hall, Vincent Square, on September 16 must be pronounced a great success, if, indeed, for the season of the year it does not establish a record. Everywhere the huge banks of flowers demonstrated the wealth of the Rose in autumn, given a favourable opportunity. Incidentally, it was an object-lesson of surpassing value to the lover of the flower—and who does not appreciate a good Rose at any season?—as to what to plant, the difficulty being to limit the choice. There were Roses galore from the leading English growers, from Newtownards, Belfast, far-off Aberdeen and other places, and the great hall was redolent with their perfume. The day, however, was oppressively hot, and many flowers had opened their "eyes" in wonder. Two novelties were deemed worthy of the gold medal, and these came from Ireland. Following is a report of the more important classes.

NURSERYMEN.

For thirty-six exhibition blooms, distinct varieties, nine entered, the first prize being awarded to Messrs. Alex. Dickson and Sons, Newtownards, Ireland, for a capital lot, *Mrs. George Norwood* (pink, very fragrant), *Alexander Hill Gray* (yellow), *Edward Bohane*, *Snow Queen*, *Hugh Dickson* (fine red), *Gloire de Chedane Guinoisseau* (vermillion red), *George Dickson* (red, very handsome), and *Bertha Gaulis* being among the best. Second, Messrs. J. Cocker and Son, Aberdeen, whose best blooms were *Gloire de Chedane Guinoisseau* (silver medal), *Snow Queen*, *Coronation* (flesh colour), *Avoca* (fine red), *Charles J. Grahame*, *Hugh Dickson*, *Mrs. S. Clark* and *A. H. Hartman*, all of high colour. Third, Messrs. B. R. Cant, Colchester, whose flowers were smaller though neat and good. *Mrs. Foley Hobbs*, Dr. O'Donel Browne (carmine) and *George Dickson* were superb in this lot.

Twelve exhibition Roses, Teas and Noisettes: First, Mr. G. Prince, Oxford, who had *Mme. Constance Soupert* (yellow, pink tinged), *Mme. Jean Dupuy* (yellow), *Alexander Hill Gray* (silver medal) and *Molly Sharmar Crawford* as the best. Second, Mr. J. Pigg, Royston, Herts, whose best were *Mme. Cochet*, *Maréchal Niel* and *W. R. Smith* (white). Mr. G. Longley, Rainham, Kent, third. His *Miss A. de Rothschild* (deep yellow) was very good.

For five baskets of exhibition Roses, distinct varieties, the first prize went to Messrs. Chaplin Brothers, Waltham Cross, whose set comprised *Alexander Hill Gray*, *Hugh Dickson*, *Snow Queen*, *Caroline Testout* and *George Dickson*. Second, Messrs. J. Cocker and Son, Aberdeen, who staged *Avoca*, *Mrs. J. Laing* and *Coronation* (flesh), Messrs. *Hugh Dickson*, Belfast, third.

For twelve blooms of any Rose in a basket Messrs. *Hugh Dickson*, Limited, Belfast, were first, staging *Hugh Dickson* very finely. Second, Mr. G. Prince, Longworth, who had a superb dozen of *Mrs. Foley Hobbs*. Third, Mr. G.

Longley, Rainham, Kent, with *Snow Queen*. There were ten competing.

For twelve distinct varieties of Perpetual-flowering decorative sorts, not more than seven stems of each, Messrs. Alex. Dickson and Sons, Newtownards, were first, having *Duchess of Wellington*, *Mrs. Wemyss Quinn*, *Red Letter Day*, *Mrs. A. Tate*, *Old Gold* and *Harry Kirk* as the best. Second, Messrs. *Hugh Dickson*, Limited, Belfast, whose *Duchess of Wellington*, *Oriflamme*, *Darkness*, *Nellie Parker* (cream) and *Prince Charming* were good. Third, Mr. G. Longley.

Six distinct varieties as above: First, Mr. Elisha Hicks, Twyford, Berks, whose *Mme. Antoine Mari*, *Florence Haswell Veitch* (fine red), *Old Gold*, *L. C. Breslau* and *Mrs. John Foster* (Hybrid Tea, red) were excellent. Second, Mr. G. Lilley, Yiewsley, Middlesex, whose Mr. *George Shawyer*, *Lyon* and *Mrs. A. R. Waddell* were very good. Mr. G. Prince, third.

The class for nine baskets of cut Roses, distinct, was one of the features of the show, four exhibitors staging in excellent form. Messrs. *Hugh Dickson*, Limited, Belfast, were first with a superb lot comprising *Lady Pirrie*, *Princess Charming*, *Golden Spray*, *Mme. Edouard Herriot* (very good colour), *Irish Elegance*, *Mrs. Hugh Dickson*, *Mrs. Robert Watson*, *Ulster Standard* and *Mrs. George Shawyer*. Second, Messrs. *Chaplin Brothers*, Waltham Cross, who staged *Lyon Rose*, *Mrs. H. Stevens* (fine white), *Ophelia* (very beautiful), *Louise C. Breslau* and *Duchess of Wellington* very finely. Third, Messrs. *A. Dickson and Sons*, Newtownards.

In the class for five baskets of cut Roses, distinct, there were eight competitors, Mr. Elisha J. Hicks, Twyford, taking the lead with *Joanna Bridge* (cream), *Irish Elegance*, a glorious basket of the single crimson *Princess Mary*, *Marie van Houtte* and *Comtesse du Cayla* (very charming). Second, Mr. *Walter Easlea*, Eastwood, Essex, whose *Lady Hillingdon*, *Lady Pirrie*, *Mme. Edouard Herriot*, *Mrs. H. Stevens* and *Ophelia* (salmon flesh) were all good. Third, Mr. G. Prince.

For twenty-four distinct varieties, decorative sorts, only two entered, Mr. J. Mattock, Oxford, being first with a good lot. *Irish Elegance*, *Marquise de Sinety*, *Louise C. Breslau*, *Beauté de Lyon*, *M. Paul Lede*, *Mme. Edouard Herriot*, *Irish Glory*, *Marie van Houtte*, *Maharajah*, *Irish Flame* and *Sunburst* were the best. Second, Messrs. *F. Cant and Co.*, Braiswick Rose Gardens, Colchester.

Twelve distinct varieties as above: First, Mr. Frank Spooner, Horsell, Woking, who staged *Sunburst*, *Ecarlate*, *Rayon d'Or*, *Lady Pirrie* (very good colour), *Mrs. H. Stevens* (fine white), *Chateau de Clos Vougeot* and *Florence Haswell Veitch* very well. Second, Mr. Elisha J. Hicks, Twyford, whose *Princess Mary* (single, crimson), *Lady Hillingdon* and *Duchess of Wellington* were excellent. Mr. G. Prince was third. Five competed.

Twelve distinct varieties of Dwarf Polyantha Roses: First, Messrs. *F. Cant and Co.*, Colchester, who had *Eugénie Lamesch* (orange yellow), *Leonie Lamesch* (orange and red), *Frau Cecile Walter* (white, cream centre) and *Etoile de Mai* (cream). Second, Mr. Elisha J. Hicks.

GROUPS OF ROSES.—NURSERYMEN.

For a representative group of Roses on a floor space not exceeding 150 square feet, only one exhibitor, Messrs. *Hobbies*, Limited, Dereham, staged, and were awarded first prize for an admirable lot. The arrangement consisted of a groundwork of Dwarf Polyantha sorts, with bold vases and stands and groups margined with *Isoplepis gracilis* and Ferns. *Rayon d'Or*, *Pharisæe*, *Mrs. A. Tate*, *Snow Queen*, *Lady Hillingdon*, *Sunburst*, *Lady Pirrie*, *Florence Haswell Veitch*, *Mme. Edouard Herriot*, *Melody*, with handsome vases of *Effective* and *George Dickson*, were among the finer items.

For a representative group of cut Roses, space 18 feet by 6 feet, for which the first prize was the society's gold medal and 40s. cash, Messrs. *W. and J. Brown*, Peterborough, were first with a superb bank of flowers, chiefly in vases and stands. *Mme. Jules Gravereaux*, *Lady Pirrie*, *Mme. Edouard Herriot*, *Mrs. H. Stevens* (white), *Duchess of Wellington* (rich yellow) and *Lady Hillingdon* were among the most telling. Second, Mr. *John Pigg*, Royston, Herts, who made a great central display of *Mme. Edouard Herriot*, employing several hundred flowers, across which a windmill-like arrangement of *Molly Sharmar Crawford* was placed. Third, the Rev. *J. H. Pemberton*, whose group comprised Polyantha sorts, largely of his own raising.

For a representative group of cut Roses, on staging space 20 feet by 3 feet, three competitors entered, the leading prize being secured by Messrs. *G. Jackman and Son*, Woking, for an admirable lot. A few good things were *Willowmere* (salmon pink), *Mme. Jean Dupuy*, *Mme. Edouard Herriot*, *Peace* (deep cream), *Kaiserin Augusta Victoria* and *Lady Hillingdon*. Second, Messrs. *B. R. Cant*, Colchester, whose stand of *George Dickson* was very fine. *Red Letter Day* and *Alexandra Zarifi* (single, of peach and cream colour), were also good. Third, Messrs. *Harkness and Co.*, Hitchin.

MISCELLANEOUS.—NURSERYMEN.

Thirty-six distinct varieties, not fewer than three stems of each: First, Messrs. *F. Cant and Co.*, Colchester, whose superb lot included *Rayon d'Or*, *Richmond*, *Joseph Hill*, *Lady Hillingdon*, *Arthur R. Goodwin*, *Alexander Hill Gray* and *Ecarlate*, all very fine. Second, Mr. *J. Mattock*, whose best were *Marie van Houtte*, *La Tosca*, *Marquise de Sinety*, *W. R. Smith* (cream, pink tinged), and *Harry Kirk* (good yellow). Third, Messrs. *B. R. Cant and Sons*.

Twelve distinct varieties as above: First, Mr. Elisha Hicks, who had a grand lot of flowers, particularly of *Princess Mary*, *Lady Hillingdon*, *Mrs. Wakefield Christie-Miller* (fine pink), *La Tosca* (pink), and *Mrs. Charles Reed* (flesh and cream). Second, Mr. G. Prince, Oxford. Third, Mr. *C. Turner*, Slough, *Mme. Jean Dupuy* being very good.

THE GARDEN.

No. 2289.—VOL. LXXIX.

OCTOBER 2, 1915.

NOTES OF THE WEEK.

OUR NEW EDITOR.

APPOINTMENT OF MR. HERBERT COWLEY.

THE Proprietors of THE GARDEN have pleasure in announcing that the vacancy in the editorial chair has been filled by the appointment of Mr. Herbert Cowley. As Assistant Editor he has been for five years an able coadjutor to the late Mr. Harvey, and may be relied upon to maintain the high traditions of horticultural journalism which have always marked the conduct of THE GARDEN.

Mr. Cowley has been serving with the "London Rangers" 12th County of London Regiment since the outbreak of war, and lately returned from the Front with a wound, which has, happily, healed. It has left him, however, with a stiff leg, which will prevent him again going on active service, and the military authorities have now "demobilised" him. His varied and successful career will be known to many, and it has been of a nature to fit him peculiarly for his responsible post, because it has covered many activities both in the theoretical and practical sides of horticulture.

Associated for many years with the work at the Royal Gardens at Windsor and the National Establishment at Kew, Mr. Cowley studied at Swanley Horticultural College in the days before it was wholly devoted to lady students, and has travelled in Eastern Europe making an extensive tour throughout Bulgaria in 1911 in search of new and rare plants. The Proprietors therefore feel that Mr. Cowley is assured of a very hearty welcome from the readers and correspondents of THE GARDEN, and hope that they will make full use of his services by applying to THE GARDEN freely for advice in any problems that may arise, no matter what the branch of gardening may be.

Wasps and Late Plums.—These insects are very troublesome with late Plums which may be left hanging outdoors. To try to prevent them being so destructive, bottles containing beer or syrup and water should be hung on the trees. This generally reduces their numbers considerably.

An Autumn-Flowering Sea Pink.—One of the most delightful plants for the rock garden in

requested to notify any change of address, since the 1915 edition was published to the Editor of the "Horticultural Directory," 10, Essex Street, Strand, London, W.C.

The Chaste Tree (*Vitex Agnus-castus*).—Having the popular name of the Chaste Tree, this shrub is a native of the Mediterranean region. In the South and West it is hardy in the open, but in many localities the protection of a south or west wall is desirable. At the present time the plants are clothed with slender racemes of pale mauve or violet blossoms, which are pleasingly fragrant. A light loamy soil is desirable, and this should be well drained. Increase is by cuttings and layers. *Vitex Agnus-castus* belongs to the Natural Order Verbenaceæ, and is allied to the Scented Verbena or Lemon Plant (*Aloysia citriodora*).

Vegetable Trials at Reading.—By way of demonstrating the great value of growing vegetables from seed sown late in the year, Messrs. Sutton and Sons are conducting experiments of a very instructive nature in their trial grounds at Reading. There are splendid rows of Cabbage Lettuce, Endive, Radishes, Onions, Beetroot, Turnips, Peas and Carrots, all of which have been grown from seed sown on July 31. From the time of sowing the plants had received no special treatment beyond thinning; they had not been transplanted or watered. True, the season has been favourable, but the weight and quality of the produce within eight weeks of the time of sowing are quite remarkable.

War Horticultural Relief Fund.—This fund to assist horticulturists in the countries of our Allies to re-establish their businesses when Peace is restored is making quiet progress. It is rather an interesting fact that to-day (September 23) the total amount received in donations and promises of donations is £5,555 5s. 5d.

—W. WILKS, *Secretary, Royal Horticultural Society.*

Apples and Pears for Wounded Soldiers.—Last year we inserted an appeal for Apples for the Victoria Hospital, which met with a most generous response from our readers. We learn from a contributor that Apples and Pears, for eating or cooking, would be very much appreciated by the wounded soldiers. Any gifts addressed to the Matron, Victoria Hospital, Tite Street, Chelsea, will be gratefully acknowledged.

A PRETTY AUTUMN-FLOWERING SEA PINK, *ARMERIA FASCICULATA*, NATIVE OF SARDINIA.

autumn is *Armeria fasciculata*. From a dense tuft of greenery peculiar to Thrift or Sea Pink arise long, slender stems, bearing heads of lovely soft pink flowers. Our illustration is reproduced from a photograph taken in the rock garden at Kew late in September. It is a native of Sardinia, and, although little known, is certainly one of the prettiest of the Sea Pinks.

"Horticultural Directory" for 1916.—The "Horticultural Directory" for 1916 is now in course of preparation, and head-gardeners are respectfully

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Covered Chains for Roses.—When visiting a garden in Gloucestershire a few days ago, I noticed in the Rose garden a large circle of Roses with Fir posts, and chains from one post to the other. These chains were hidden by short sections of hollow wood, Bamboo or Birch, each section being about 6 inches long. Do you consider this to be any improvement on the ordinary chain for Rose growing?—WEST COUNTRY. [Iron chains may be harmful to the growth of Roses in very hot or in very cold weather, although we are not aware that such is the case. We welcome correspondence on a subject of so much importance to all who grow Roses.—ED.]

Cotoneaster Simonsii.—As a hedge plant this Cotoneaster is not used as extensively as it deserves to be. When trained it makes a fine wall plant, and the one referred to by Mr. Charles Comfort in THE GARDEN, issue September 18, page 456, which has attained a height of 20 feet, proves its worth for the furnishing of high, exposed walls. In the Southern Counties there are some beautiful hedges of it. For use as ornamental division hedges in gardens this Cotoneaster is most serviceable. The plants make fibrous roots freely, and so it is necessary to deeply trench the soil in which they are to be grown. I have seen fine hedges of the plants growing in almost pure sand.—SOLENT.

Economy of Rockwork and Garden Literature.—"C. H. S., Alderley Edge," in replying to my "Economy of Rockwork" in a recent issue, contrasts a garden and a library, and asserts the garden appeals only through the eye. All horticultural literature disproves this. Gardening is as much a cult of the mind as any other cult not purely abstract. It pleases the eye, no doubt, but it is equally true that it pleases the mind when the eye is not in action, and literature is an intermediary which assists both. The original success of THE GARDEN was due to the realisation of the true place of literature in the garden. THE GARDEN met the mind and made all accessories secondary. It gave plants as the essential, not news about them. THE GARDEN opposed the exotic system of a maximum display to the eye and a minimum to the mind, which the bedding out of the early seventies involved. Since then much has changed, but the present popularity of rockwork is a legitimate development of THE GARDEN's original programme.—HURSTCOT.

Birds and Ripe Fruit.—When I wrote my note on this subject the wasp season had not commenced. I mainly referred to birds and soft fruits. But I quite agree with "T. A. W.," page 457, issue September 18, that the wasps are terrors. The birds, I find, generally peck such fruits as Apples and Pears on the side or near the fruit-stalk first, and then the wasps get busy there also. But in the case of Plums, Grapes, Peaches and Nectarines they do not wait for birds to make an inroad first, but make it themselves. Wasps are, in some years, much more numerous than in others, and this is one that appears to be generally favourable to them throughout the country. The queen wasps, I am told, are bred during the last six weeks of their season of nesting, so that all nests now should be destroyed. I use a piece of rag rolled to the size of one's finger, soak it in

turpentine, place it in the entrance hole of the nest, and put on a spadeful of earth after sunset. All wasps at home remain there.—G. G.

Antirrhinums as Bedding Plants.—It was with pleasure that we read "G. G.'s" note (issue September 18, page 457) on Antirrhinums being so largely used in the Bournemouth Public Gardens and district. He is quite right in his surmise about "their cultivation being increased considerably next year," for we unhesitatingly say they are to be the bedding plants of the near future now they can be had in so many beautiful art shades, and may be relied upon to come true from seed when obtained from a reliable source. There is one point, however, with which we must disagree; that is, the proposal of saving the seeds of the very fine strains in the private garden. It was this haphazard method of seed saving that kept these beautiful flowers so much in the background; one never knew what to expect, for they will not produce any true colour form unless specially bred. This is our experience of years of labour. We strongly advise amateurs not to save the seed, or they will be terribly disappointed with the results. By all means take cuttings; these will bloom much earlier in the year, but will not make such fine plants as seedlings or give such a succession of bloom.—W. H. SIMPSON AND SONS, Birmingham.

Meconopsis heterophylla.—This is said to be the only species of that genus from the New World, being found in America. It is one of the most lovely of the genus—and, as so often happens with the beauty of the family, is a "pernicketty" tempered, easily offended creature. So long as this Poppy gets its own way, it smiles and is a joy to see; but if you interfere with it, sulks and pouts will certainly be produced. All goes well with it if it is allowed to sow itself and it does not get crowded out by stronger-growing plants. Then there should be a mass of the glorious deep orange flowers throughout May and June, of a colour that is as rare as it is beautiful. Each flower has a deep maroon eye that greatly adds to its beauty. This season the heavy rains of July have caused seedlings to spring up earlier than usual, and the warm, sunny days of the last month have induced them to run up into flower. We are enjoying a second crop of the brilliant flowers, and are rather afraid that we shall have few, if any, non-flowering rosettes that will go through the winter to bloom next year. Spring-sown seeds never do so well as autumn self-sown ones, and if raised in pots it is most difficult to plant out the young plants unless the whole potful can be put in without disturbing any of the roots.—E. A. BOWLES, Waltham Cross.

The Dwarf Pomegranate.—In the interesting article on the Pomegranate which appeared in THE GARDEN, September 18, page 462, no mention is made of the dwarf form. [It has since been referred to by Mr. E. A. Bowles on page 468, issue September 25.—ED.] It is one of the most distinct and floriferous of all the varieties, and, owing to the fact that it blooms freely in a small state, a place may be found for it in gardens where the ordinary form grows too tall. The Dwarf Pomegranate, the botanical name of which is Punica Granatum nanum, forms a dense twiggy bush from 3 feet to 5 feet in height, clothed with small leaves, which in the autumn, just before they drop, change to a bright golden yellow tint, but they do not long remain in that stage. The flowers in the bud state are of a bright red colour and wax-like substance, but, when expanded, the

exposed interior is of a rich glowing orange tint. Towards the end of the summer and early autumn this Pomegranate is very attractive, as the blossoms are borne with great freedom. According to Loudon, the Dwarf Pomegranate was introduced in 1723, but it is not very generally met with. Plenty of sunshine is necessary to its well-doing. From its lowly stature it may be trained against the wall of a hothouse facing south. In such position a very fine specimen stood for years in the Ashburnham Park Nursery of the late Mr. William Bull at Chelsea, but the spot is now covered with dwelling-houses.—H. P.

The "Daily Mail" Show of Vegetables. I came away from this wonderful show with very mixed impressions. For the life of me I could not understand why none of the varieties were allowed to be named. This fact made the exhibits of small educational value to those who came to see the show. The fact that the exhibit of Mr. Tom Jones, one of the £100 prize winners, had to be staged in an ugly box made it look far less impressive than it would have done had he had as much exhibition latitude as was accorded the professional gardeners in their class, though his material was certainly nothing inferior to theirs in quality. Among a lot of good things shown were the Carrots from Mr. T. Rule Owen of The Glen, Haverfordwest. In a fairly long experience, I must say I never saw anything quite so fine, so even, so clean, and so beautifully grown. A well-known vegetable grower who was examining them with me hazarded the opinion that they were perhaps the best lot of Carrots ever put up at any show, and I think he was probably right. Here, again, I wonder what the variety was. I suspect, but I do not know.—F. HERBERT CHAPMAN.

Solanum jasminoides.—Although usually referred to as a greenhouse climber, I propose in the present note to call readers' attention to it as an outside plant. It cannot be claimed as hardy in every part of the United Kingdom, but there are many counties and a host of positions where it would thrive. I recently saw a beautiful sight in Gloucestershire, where this Solanum and Vitis Coignetiae were growing intermixed around an old tree. The pretty clusters of almost white flowers of S. jasminoides among the bold foliage of the Vitis were most effective. To secure the finest results a southern aspect should be chosen, and for preference a light, warm soil. The position has much to do with success or otherwise, because the more sunshine the plant receives, the riper the wood becomes, and it is not so liable to be injured by frost. Little pruning is required beyond cutting out a small portion of the old wood if the growth is too thick. S. jasminoides begins to bloom in early summer, and at the present time it is still a mass of flower. In fact, it will continue more or less until cut down by frost. The pity is that it is not quite hardy, but if allowed to ramble at will over a warm wall, or grown in association with other climbers it is a charming plant.—B.

Changing the Botanical Names of Plants.—I had occasion recently to refer to the list issued by the Royal Horticultural Society of the "Plants &c., Certified by the Society from 1859 to 1910 inclusive." The names of the Ferns contained therein furnish a good illustration of the chopping and changing about that is so frequently indulged in by some botanical authorities, and the superseding of old and established names by new ones. The average horticulturist is apt to look upon it as designed either to puzzle those outside of the

scientific world or to enable the author to pose as the authority for the various changes. That the common Brake or Bracken is no longer a *Pteris*, but a *Pteridium*, and in the case of the Hart's-tongue Fern, *Scolopendrium* is superseded by *Phyllitis*, will be news to many. This, however, is not all, as the Male Fern is now a member of the genus *Doryopteris*, while *Todea* is changed to *Leptopteris*. Those pretty hardy Ferns *Onoclea* and *Struthiopteris* have now a fresh genus made for them in the awkward-sounding word *Matteuccia*. In the preface it is stated that in the Ferns Carl Christensen's "Index Filicum" has been followed. Surely the Royal Horticultural Society should have been patriotic enough to retain the names given by those good English botanists who have made a special study of Ferns.—H. P.

Crinums.—It is interesting to notice that these plants are gradually gaining favour. We have been successful in flowering *Crinums* the first season. Large, well-ripened, dormant bulbs were purchased early in April, 1914. These were potted into 8½-inch pots, which were just large enough to allow a small quantity of good loam to be rammed around the bulbs, but the upper half remained fully exposed. The pots were then buried in a border under a south wall, and soil was heaped up over the exposed portion of the bulbs. Growth of leaves quickly commenced. Water was applied copiously during dry weather, and by the middle of August the first flowers appeared. Some of the roots produced two spikes of flowers, while not one failed to produce abundance of healthy foliage and at least one fine head of flowers. During October the plants were lifted for removal to their permanent quarters. It was found that the pots were full of roots, but very few had reached the soil surrounding the upper half of the bulbs. They were removed from the pots and planted in a narrow border having a south aspect. The soil is a light rich loam. There has been an abundance of flowers during August and early September. Deep planting (as the term is generally understood) has not been practised; the base of the lower leaves is resting on the surface of the soil. The above remarks apply to the variety *Powellii album*.—C. RUSE, *Folly Farm Gardens, Sulhamstead, Berks.*

Crocus Species.—How Mr. A. Ireland must have chuckled when he saw the appeal of the Rev. Joseph Jacob to grow such *Crocus* species as *Sieberi*, *biflorus*, &c. (issue September 18, page 464.)! Mr. Jacob is so innocent of such matters that he does not realise that Mr. Ireland and the firm he represents, to say nothing of Mr. Bard, are in the habit of exhibiting not merely for the love of the thing, but for business. That being so, it stands to reason that firms are not going to make a big splash with things that cannot pay their way. Even granting that *Crocus* species are

beautiful, they cannot match the large-flowered Dutch type.—T. A. W.

Burning Leaves.—I was very glad to see the article by "G. G." on page 445, issue September 11, on "Tree Leaves." It is a most wasteful thing to burn any leaves which will make tolerable leaf-mould, or which can be used for the making of hot-beds and other garden purposes, but, of course, leaves of such trees as *Poplars*, *Sycamores* and *Planes*, which are quite useless for most purposes, should be burnt to get rid of them, and the ash, which is valuable, stored in sacks in a shed before it gets wet. Shrub leaves also

THE "LILY OF THE FIELD."

(*STERNBERGIA LUTEA*).

must be burnt, as they are useless, and, with the leaves, hard rubbish from the borders and weeds which are seeding should also be got rid of. Here we find that leaves may be mixed with soft garden rubbish, and, after this has rotted a few months, good vegetable manure is formed. But we shall not waste many leaves in this way this winter (if it can be called waste), for we shall want to use up all possible leaves for the making of leaf-mould. Leaf-mould and semi-rotted leaves will be more than ever in demand as manure, both during this and next year, for stable manure will be hard to get with so many horses being taken out of England to serve at the Front.—E. T. E., *Sheffield.*

STERNBERGIA LUTEA.

FOLLOWING closely upon the heels of the Meadow Saffron and Autumn Crocus are the *Sternbergias*—of which *S. lutea* is the supposed "Lily of the Field" of Scripture—a small though valuable group of autumn-flowering bulbous plants belonging to *Amaryllideæ*. The undoubted beauty of the plants—and those best known in particular, chief interest being invariably centred in *S. lutea*—commend *Sternbergias* to all who see them. Some are spring and others autumn flowering, though the former by no means compare with the latter in point of popularity. The spring-flowering form of *S. lutea*, known as *fischeriana*, is a plant very much like some of the ordinary forms of *S. lutea*, but it is a spring-flowering kind. At the same time, it does not command the attention that is sure to be given to autumn-flowering forms. We well remember the interest that a small exhibit of *S. lutea* created some years ago when shown by Mr. Hudson, gardener to Mr. Leopold de Rothschild, at one of the meetings of the Royal Horticultural Society. The way these were set up was excellent, because it was an object-lesson of how small groups of these plants appear in Nature.

All who would care to grow *Sternbergias* will be pleased to know that the plants offer but very few cultural difficulties. The chief one, and hard to overcome, is a certain shyness of flowering, to which the plants on certain soils are prone. Not unnaturally, we have largely, if not, indeed, entirely, to depend upon imported bulbs of these plants year by year, and as these are invariably small in size, cultivators should be made aware of the fact that probably three years are required before these may be called fully established. In all probability the first year no foliage will appear, a most weakening influence on the bulb, to say the least. Still, with the knowledge that the subject is well planted, it would be unwise to disturb them at this time and for this

cause. In the Thames Valley, on a light and well-drained soil, a soil extremely dry, too, in summer, the *Sternbergia* gives little trouble, the imported roots becoming well established in a couple of seasons, and from this time dates the increase of the bulbs below ground. Where the soil is heavy and inclined to clay, it is best considerably lightened by grit, leaf-soil and the like, and this to a good depth. In all cases the bulbs of these should be planted deeply, 6 inches below the surface not being a bit too deep, and when planted leave them alone, for few plants are more opposed to frequent disturbance than these winter Daffodils, as they are called. In view of this it is

a good plan to place them in positions not exposed to yearly interference, and among worthy places warm, sunny banks or slopes may be named, for here it would be not only possible, but quite easy to establish them. It may be well to dig out and replace the original with fresh soil in such places, but much depends on the material itself and a good medium, as before described. A good time for planting dry bulbs is early in August. There is a form of *S. lutea* called *angustifolia* which is less shy in its flowering, and, indeed, when established may be regarded fairly reliable in this respect.

S. lutea, of which a small group appears in the illustration on the previous page, is among the oldest of cultivated garden flowers. There are several varieties, the one named above and *S. l. major* being the best of the autumn-flowering section. The last named has flowers of the richest yellow and does not remain in the cup form, but, casting first one segment and then another, opens eventually into a large bloom of rather flat shape, save for the slightly upturned margins. *S. l. fischeriana* is an early-flowering kind, often appearing in February or soon after. All the autumn-flowering forms of *S. lutea* produce the foliage at the time of flowering. Another very important species is *S. macrantha*; this also flowers in autumn, and sends up the leaves in early spring. It is a large and bold-flowering kind, less refined, perhaps, than *lutea* forms generally, though quite double the size. It is possible it is less hardy than some, as a small planting made a year or two back never came up again, though planted at much the usual depth for such things. The bulb of this is also very large. Another species not usually seen in cultivation is *S. colchiciflora*. This is also an autumn-flowering kind, though of diminutive growth when compared with the forms of *lutea*. The flowers are rich yellow in colour, and the perianth segments little more than an inch long.

A NARCISSUS FOR THE ROCK GARDEN.

DURING the early days of spring *Narcissus minimus* is one of the daintiest flowers in the rock garden, and one that never fails to create interest among visitors. This is a perfect little trumpet Daffodil in every respect, yet it seldom grows more than 3 inches high and the flowers do not exceed three-quarters of an inch in diameter. The colour is golden yellow, and the plant is by no means difficult to grow. The bulbs, which are about the same size as those of the ordinary Snow-drop, should be planted 2 inches to 3 inches deep giving them a well-drained nook in the rock garden. This little Daffodil needs well-drained loam for a rooting medium, and the bulbs should be planted now in colonies of a dozen or more, according to the space available. Isolated plants lose half their charm. It was, I believe, first found growing wild in Spain by the late Peter Barr about thirty years ago. As most of the bulbs sold now are collected from their native places, they cannot all be relied upon to flower the first year, though a good many of them do. Once established, they come up and flower year after year in many gardens, though in a few instances one hears of them dying out.

H.

THE BEST BERRIED TREES AND SHRUBS.

AT this season of the year, when our hedgerows are resplendent with the brilliant fruits of the Wayfaring and Spindle Trees or the more sombre hues of the common Hawthorn, it seems opportune to draw attention to the goodly host of shrubs that are worth including in our gardens for the sake of their fruits alone. It is a curious trait of Nature that many of our best berried trees and shrubs, notably the Holly

THE NEW BERBERIS BREVIPANICULATA WITH CLUSTERS OF ORANGE AND CRIMSON FRUITS.

and Sea Buckthorn, have flowers of an inconspicuous character; hence, were it not for their fruits or foliage, one would find but little use for them, even in the largest shrubberies. The autumnal and winter beauty of such shrubs has not in the past been considered so fully as it might have been, and too often little more than a passing thought is given them when planting is done. Yet they have their value from now onwards, when the autumn flush of flowers is on the wane; and some of the best are mentioned here as a reminder to those who anticipate planting shrubs this autumn. Generally speaking, they will thrive in any good garden soil, but the best

effects are usually obtained by grouping the smaller-growing kinds in masses instead of planting them as isolated specimens.

The most interesting family of all is the Symphoricarpaceae, or Snowberry, of which, until quite recently, *racemosus* was the best example; but a year or two ago one named *occidentalis*, with much larger fruits, was shown. Both have glistening white berries, that look very charming just now, particularly if the shrubs are grouped in front of some dark-hued evergreens such as Yews. *Crataegus Pyracantha Lelandii*, though usually grown on a wall, is much more effective as a free shrub, in which form its large clusters of orange scarlet fruits give a pleasing pendulous habit to the branches. To crucify this plant on a red brick wall, as is so often done, is the acme of bad taste, and ought not to be tolerated in any garden.

The Sea Buckthorn, already referred to, is one of the most beautiful of all our fruiting shrubs, though perhaps its semi-transparent, pale orange berries are more appreciated in the winter. In planting this we must remember that male and female flowers are produced on separate bushes, and to get a display of fruits one pollen plant to about three of the other sex must be included. This also applies to the *Skimmias* and *Aucubas*, both of which will give us scarlet fruits in abundance if this little, though important, law of Nature is attended to. The *Cotoneaster* family is particularly rich in ornamental fruiting shrubs, and, common though it is, the one named *Simonsii* is the best that I know for retaining its berries through the winter. *C. frigida* makes a tall shrub some 20 feet high, but is very beautiful just now with its good-sized bunches of red fruits. A new species named *C. applanata* gives promise of being particularly useful on account of the freedom with which it produces its fruits.

Among the *Berberises*, or Barberries, there are several well worth growing for the fruits that they bear. The common species found in our hedgerows, and named *vulgaris*, is very handsome with its pendulous clusters of coral red, sausage-shaped berries; but the newer *Wilsonæ* is even more charming, as it has a graceful, semi-pendulous habit and long spines that render it attractive at any season of the year. Another new species that is very beautiful at Kew just now is *B. brevipaniculata*. It has large clusters of almost globular, small fruits, the colour of which is a curious combination of orange, scarlet and crimson. It forms a neat shrub, and will doubtless be extensively planted when better known.

In the Prickly Heath (*Pernettya mucronata*) we have a dwarf evergreen shrub that likes peat in the soil, and which, if well grown, will give us a wealth of globular berries. Some of these are a delicate shade of rose pink, others nearly crimson, and others, again, ivory white, these variations at times being found on the same plant. If grouped among such shrubs as *Rhododendrons* the Prickly Heath makes a charming feature at this season. Among *Roses*, there are several well worth growing for their fruit alone, one of the best being *Rosa Moyeii*, a rather new single-flowered species, the fruits of which are Pear-shaped and of a brilliant red hue. The *rugosa* *Roses* and the common Sweet Briar are others that come to mind as useful in lending

gleams of colour to the landscape from now onwards well into the winter. In addition to the shrubs now named there are many which have ornamental fruits; but enough has been said to draw attention to a class of plants that is, in the rush for those with brilliant flowers, too often overlooked.

THE MICHAELMAS DAISIES

THE thanks of all lovers of autumn flowers are due to those enthusiasts who must have given much of their time and patience to bring about such a great improvement in this indispensable race of hardy plants.

It seems but a few years ago since the plants were considered of such little importance that it was seldom they were given much prominence, their chief use in many instances being to block out unsightly corners, and to dump them down in the shrubbery wherever they could be placed without much trouble. This course was to a certain extent understandable on account of the inferior quality of the then-known varieties. But poor as they were in comparison with some popular varieties to-day, they had not a chance to show what effect they were capable of producing, as there were few who thought it worth while to devote a little time with the spade, and least of all anything in the shape of manure, to their surroundings.

This haphazard method has, however, altered with the improvement of the race, and, even in places where they were slow to import the new additions, the effect of well dug and manured ground became evident on the old stock when, in responding to the demand for the more gorgeous of hardy plants, a few were made use of to fill in the background of a newly made border, which was, of course, duly prepared in a proper manner. Thus, in not a few cases the merits of the Starworts came to be realised, and the demand was there for the newer forms as they were introduced. At Kew Aster Robert Parker and the Italian Starwort (*A. amellus bessarabicus*) are naturalised in bold groups in the woodland with telling effect.

In addition to the position usually allotted to them in the herbaceous border, the opportunity of massing them alone and in conjunction with the border Chrysanthemum has been seized, the result being an effect equal to any of the season, as both flower at the same time, and the bright colours of the Chrysanthemum, especially the Massé family, are seen to great advantage, on rising ground particularly, among the blue and violet shades of the Daisies. For this or any other scheme of planting to be successful, it must be understood that all the Starworts appreciate a good deep soil that has been well enriched with manure, as they are very vigorous in their root action. They must also have ample space, so that each shoot may appear to the best advantage. It is a poor method to have a plant tied in the middle like a wheatsheaf; the beauty in such a

specimen is completely lost, besides being a most wasteful practice, as, instead of each main stem having vigorous side shoots down to the ground, there is nothing worth cutting but inferior bunches at the very top. From a well-grown plant, one to three shoots neatly staked out will give a far better return in a more graceful manner than three times their number badly grown and overcrowded. This method entails a severe thinning out of the shoots in early spring, which may perhaps appear rather wasteful to those who have not as yet experienced the effect in September; but once it is tried, the superiority of the sprays that are available for cutting will alone render the old bunching-up process a thing of the past.

When alluding to these plants in their different species and varieties, one often hears a distinct murmur to the effect that all of them take after one another, or, in other words, are too much alike—

trusses and reaches a height of about four feet. In *A. ericoides* we have a section of special value for cutting, on account of its long and graceful sprays being available in colours that are always in demand. A beautiful pink is *A. e. Charmer*, growing some three feet high. *A. e. Enchantress* is a white that passes to pink with age. A beautiful shade of lavender is *A. e. superbus*, while *A. e. The Pearl*, bluish white, is indispensable.

Of quite a distinct appearance from the foregoing are the varieties of *Novæ-Angliæ*. They are of a more vigorous habit and the flowers are larger; they can also be relied upon to bloom right up to November, and what is perhaps not their least interesting feature is their considerable diversity of colour, crimson shades especially being most prominent in the varieties *Brilliant*, *Mrs. S. T. Wright* and *W. Bowman*. Blue and purple shades are seen to great advantage in *Damosel*,

ASTER ROBERT PARKER NATURALISED IN THE WOODLAND.

that if one possesses a few he can almost safely say he has them all. That there is ground for this charge cannot be denied, one reason being the ease with which they can be raised from seed. But beyond the *Novi-Belgii* species the charge has not a sure foundation, as among other species and varieties there exist a number that show great distinction, a few of which are here given. These are bound to be admired wherever perennial Asters are appreciated.

In the *Amellus* section three varieties are of outstanding merit. *A. A. Admiration* is a dwarf grower, and carries immense masses of lovely mauve pink flowers. *A. A. Beauté Parfait* is perhaps the finest of the section, with fine clusters of rich dark violet flowers with a yellow centre. *A. A. Perry's Favourite*, with rose-coloured flowers, is a charming variety and, like the last named, is of medium height. *A. cordifolius* Edwin Beckett has fine mauve flowers borne in pyramidal

Duchess of Albany and Climax. All these average about four feet in height. A beautiful white variety is *Amity*, growing some two feet high.

In the *Novi-Belgii* varieties are some interesting forms, chief among them being the double-flowered *Beauty of Colwall*. The flowers are a pleasing shade of lavender and are produced with the greatest freedom on robust-growing stems that average about four feet in height. Brightness, rosy lilac, produced in elegant sprays, is most useful. *Eileen* is a fine deep blue, and for a paler form *Margaret* is worthy of note. White Queen stands well out among the whites, and for a beautiful shade of pink *Perry's Favourite* should not be overlooked. There are other Michaelmas Daisies, but with a selection of the foregoing the garden in autumn will not be wanting in colour, nor the vases indoors be empty, so long as severe weather remains at a distance.

Rotherham.

F. J. TOWNEND.

BLUE - FLOWERED BULBS FOR AUTUMN PLANTING.

THOSE whose business or hobby it is to study the colour blending of flowers for pictorial effect realise only too well the paucity of really good blue flowers that exists. Spring is, perhaps, the most bountiful of the seasons in this colour, as in addition to the many charming little alpine of herbaceous or sub-shrubby habit, there is quite a host of bulbs that give us their quota of blue at that season. As with most other things relating to gardening, and floriculture in particular, the term blue is a very elastic one, and embraces many colour shades that the artist would find other names for. Yet it is in this very elasticity that the average flower-lover finds much enjoyment—pleasure that would be lost were every flower tabulated under a strict colour chart. Using the term blue, then, in its broadest gardening sense, there is no lack of bulbs that may be planted during the next few weeks for the purpose of providing us with drifts and clouds of blue next spring.

The most charming of these is, to my mind, the beautiful little *Chionodoxa sardensis*, a rich gentian blue flower, only a few inches high, that follows closely on the last of the Snowdrops. It is comparatively rare yet, though no more expensive than the better-known *C. Luciliae*, or *Glory of the Snow*. Although the latter has blossoms of a paler colour, it forms a very pretty companion to the richer-hued *sardensis*. Other and larger-flowered members of the family are *grandiflora* and *Imolusii*; but the last named is still rather too expensive for planting freely. Grass and woodland, shrubbery and rock garden, may be transformed into a fairyland of blue at a comparatively small cost by the free planting of the first two species named. Of very similar habit, and bearing flowers of true blue a little later in the season, is the dainty little Siberian Squill (*Scilla sibirica*). I have often seen this recommended for planting with Snowdrops, so that a contrast of white and blue might be obtained; but my experience is that the whiteness of the Snowdrops has departed before the blue of the Squill appears, especially the first season after the bulbs were planted. The Two-leaved Squill (*Scilla bifolia*) has blossoms of rather paler colour, and flowers with the *Chionodoxas*. Both *sibirica* and *bifolia* are excellent for the positions recommended for the *Chionodoxas*. While dwelling upon the Scillas, it may be permissible to mention those that flower later in the spring, usually about the month of May, when the Tulips are painting the garden with their gorgeous colours. *S. nutans* is our wild Bluebell, and needs no further description; *hispanica* or *campanulata* and its variety *compacta*, and *patula major* are three others that are very similar in habit and general appearance.

The Grape Hyacinths, or *Muscari*, are a genus of bulbous-rooted plants to which we are indebted

for some of our best blue flowers of spring. *Azureum*, sometimes known as *Hyacinthus azureum*, is the earliest to flower, and forms a sheet of Cambridge blue colour in border or woodland as early as February. March brings us the Italian Grape Hyacinth (*Muscari botryoides caeruleum*), with its dark blue flowers that always remind one of old-time gardens, and before it has

several years ago will live long in my memory. These Grape Hyacinths do not seem to thrive so well in grass as in the border or shrubbery, though they can be induced to flower fairly well in turf by renewing the bulbs occasionally. The variety Heavenly Blue, in addition to its exceptional value as a garden flower, is charming in a cut state, and will last a considerable time in water, its fragrant flowers always being greatly admired when used in this way. The two Tassel Hyacinths (*Muscari comosum* and *M. Heldreichii*) both have deep blue flowers, but neither is suitable for creating anything like a bold display in the garden. In writing of blue-flowered spring bulbs, the ordinary bedding or Dutch Hyacinths must not be omitted. In such varieties as Czar Peter, Blondin and Queen of the Blues we find pale

shades of this colour, while the varieties Charles Dickens, Grand Maître and King of the Blues give us flowers of darker hue. If we stretch our colour so as to include violet, the ordinary bedding Crocuses of that colour may be considered in any scheme of blue that may be desired during the early months of the year. Instead of striving for a blue border at one season only, as is too often the case, an effort should be made to have it at least presentable during spring, summer and autumn, and by a free, though judicious, use of the bulbs named,

the first of the three seasons would not present many difficulties. All will thrive in any reasonably good garden soil, a trait that is not yet developed in many blue-flowered plants of a non-bulbous character.

H. W.

THE ROSE PROSPECTS OF AUTUMN.

THE thorough ripening of the first wood which many of our Roses experienced during the hot summer days has, no doubt, had much to do with the glowing prospects for autumn flowers. Trim away what old wood can be spared, cutting back to the most promising young breaks and removing all spent flower-trusses. This will be found a great help towards the better development of late bloom. The following are most promising here, and cannot well fail to give us a grand show if ordinary weather prevails: Betty, Rayon d'Or, Château de Clos Vougeot, Lady Hillingdon, A. R. Waddell, Mrs. David McKee, Dorothy Ratcliff, Lyon Rose, Sunburst, Lady Pirrie, Irish Elegance, Irish Beauty, Mme. Abel Chatenay, Mme. Falcot, Marie van Houtte, Sunset, Mrs. Alfred Tate, George C. Waud, Richmond, Lady Battersea and Simplicity. This is but a short list of the best, and it could easily be doubled. Snow Queen, Victor Hugo and General Jacqueminot promise best among the Hybrid Perpetuals, and Zephyrine Drouhin is sure to be there. Among the best all through the season, and likely to continue so, are the Dwarf Polyanthas, the following being especially noticeable: Phyllis, Aschenbrödel, Mrs. W. H. Cutbush, Jessie, Orleans, Rödhätte and Erna Teschendorff. I am sorry to see so much mildew upon the stems and foliage of our Moss Roses.

Uckfield.

A. P.

CHIONODOXA LUCILIAE

SARDENSIS.

(Natural size.)

departed the most beautiful member of the whole family, known as Heavenly Blue, expands its blossoms with a freedom that we find in few plants. I know of no flower capable of creating such a wonderful and beautiful display in the garden as this Grape Hyacinth, and the sight of a long, narrow border filled with it that I saw in Surrey

NOTES ON TULIPS.

BY THE REV. JOSEPH JACOB.

WERE old Mrs. Malaprop ever to take to writing on the Tulip, she would very likely, among her other observations, say that it was a "paddlebox." The flower is such a strange bundle of contradictions. It was grown by Gerard, Parkinson and Rea, and yet it is only "coming in." It is quite easy to manage, and yet needs great care when it is growing. It is never perfect until it is "broken." It entirely vanishes, but is "all there" when lifted. It is known and unknown. Bright and dull. The foregoing are sufficient enigmas to introduce as *hors-d'œuvre* to the more practical fare which is to follow.

First, about the uses or purposes to which Tulips may be applied: Bedding, clumps in borders, rockwork, and beds in the reserve garden for cutting are those for which they are generally employed. Why, however, should not a collection be formed? I am a great believer in every gardener having a definite object or objects in their gardening, over and above the more general one of having a nice bright show of flowers or a good crop of vegetables. It gives a zest which I can only compare to the effect of a long march on the saucy appetite of a recruit. The pleasure of anticipation, of ordering varieties that are unknown, is great and alluring, and when it can be indulged in with a small expenditure of money it must appeal to a fairly wide circle of gardening enthusiasts. Pearsons of Lowdham catalogue thirty-two varieties of Cottage and thirty-one of Darwin

Tulips. Of the whole sixty-three, only one (Louis XIV.) runs into double figures of shillings per dozen; and only eight, including the above, touch or are over half a crown.

Somewhere about a guinea would purchase three bulbs of each of the fifty-five remaining varieties. There must be many readers to whom this would not be a very great extravagance, even in war-time, and such an expenditure would be quite in accord with the recent encyclical letter of the Royal Horticultural Society. It will help to "keep firms going and to meet current expenses which cannot be suspended."

Let me try to enumerate some of the utilities of a collection. To begin with, there is the joy of expectancy and the pleasure of comparison, which, once the start is made, may easily develop into hardy annuals by the yearly addition of new varieties. Then, if Tulips are required elsewhere,

it is an easier matter to select the most appropriate colours, or the shades one likes best, with the flowers under one's eyes, than if we were obliged to rely on written descriptions.

Cheap Varieties.—In my notes in THE GARDEN for September 11 I gave a list of six good cheap Darwins (Fra Angelico, Clara Butt, Pride of Haarlem, Margaret, Baronne de la Tonnaye, and King Harold or Loveliness). A companion list of Cottage varieties would be: La Merveille (orange scarlet), gesneriana spathulata (brilliant cochineal red), Golden Crown (golden yellow, edged and flushed red), Picotee (pointed white, edged and flushed rose), Bouton d'Or (deep rich yellow, a Tulip that grows very much when in bloom) and Rosalind (rose).

Hammer Hales and Boadicea.—Readers of THE GARDEN will know that there have been very

signified that it had sown its wild oats, and that henceforth it was going to settle down. But our flower is such a "paddlebox" that that is what it did not do, although to the casual observer it would appear as if it had done so. The "curious" are still nearly driven mad with its vagaries. They have evolved with much patience a hard and fast set of requirements, and every bloom must be prepared to fill them or to be put on one side. Now what is so perplexing is to have Annie Macgregor or Trip to Stockport quite all right one season, while the next they will display all manner of bad habits, such as "flushing" or "skipping." The modern Darwin grower is likewise seriously troubled from time to time with the vagaries of his flowers, but in a different way. He has bought or planted what he took to be a self-coloured variety, but when blooming-time

COTTAGE TULIPS IN AN OLD ENGLISH GARDEN.

extensive trials of Tulips, both this year and last, at Wisley Gardens, culminating in the all-Tulip Show at Vincent Square on May 13 and 14. I then became aware that there are two varieties called Hammer Hales in commerce—one, large, ill-conditioned looking and egg-shaped; the other, smart, shapely and somewhat pointed. No wonder Mr. Wallace asked me how I could "crack up" Hammer Hales in the way I do, when he had the poor one in his mind's eye. What I have previously called Hammer Hales is the same as his Boadicea, so all that I have ever said about Hammer Hales must be transferred to that variety. In future I only know Boadicea. It is one of the finest and most satisfactory Tulips grown.

Breaking.—The old florists' idea of a Tulip was that it was in a kind of hobbledehoy state until it (to use a technical word) "broke" or became "rectified." Its donning a coat of many colours

comes round he is mortified to find that it has become striped. Sometimes the dealer is blamed for sending an untrue stock, but this is unfair. The stock would be true enough, only a certain proportion have suddenly become striped or rectified when they were not wanted to do so. No one can tell why, and no one can tell when, such a change will take place. That is what is so aggravating. Numerous theories have been suggested, but not one of them seems to work. Is it lime? Is it poor soil? Is it the use of chemical manure of some kind? Is it a too frequent change of soil? When did or does the alteration take place?

In the seventeenth century a man in Brussels is said to have made a regular business of "breaking" Tulips. There is a substantial reward waiting to-day for the man who will do the reverse, *i.e.*, keep them in their self condition.

WORK AMONG THE CHRYSANTHEMUMS.

Plants for Lifting.—There are many cultivators of Chrysanthemums who do not grow large numbers in flower-pots during the spring and summer months, but grow them in boxes in the spring and then plant them in the open borders, finally lifting and potting the specimens in the autumn. There are others who cultivate many in pots as well as in the borders for lifting later on, as stated above. Where possible and convenient, the plants to be lifted should be in the bud stage when this work is done; that is, the flower-buds should be formed when the plants are lifted and potted. It is advisable to lift and pot a few at a time if a regular supply of blooms is the object, and, as we now possess so many excellent varieties, early, late and medium, there should be no difficulty experienced in securing an unbroken supply of fresh blooms.

Do not lift any plants from a dry soil, as they would fade very much for a long time after being potted, however carefully they may be treated. If the weather is dry and the plants are ready for lifting, thoroughly soak the soil at least twenty-four hours prior to lifting. If this is done, the stems and leaves will become well charged with moisture, the soil will be in a fit state to handle, and the plants will not show signs of distress afterwards. If lifted before the buds are formed and placed in houses forthwith, the stems of the plants grow extra long, are weakly, and do not bear flowers of high merit.

Have the pots in readiness, clean and of various sizes, so as to accommodate plants with many roots and those possessing fewer. With a garden fork lift the plants, preserving the roots and retaining some of the garden soil with them. Pass some good compost through a 1-inch mesh sieve and add to it some well-rotted manure; sand is not needed. In the bottom of each pot put a single hollow crock and some half-rotted leaves or rough pieces of fibrous loam, as all the space possible will be needed for the roots and new soil, which cannot be in great bulk in any case. Pot firmly, give water once and also syringe the leaves, then put the plants in a shed, or in a glass-house, and shade heavily for two days, syringing the foliage twice each day. Leave the plants in the shed two days, or on the north side of a wall or hedge a similar time, then place them in the glass structure. If the soil in the pots is kept in a medium state of moisture, new roots will soon take possession, when freer ventilation of the house, less syringing of the foliage, and shading will be required. All this careful treatment will result in the retention of the basal leaves as well as in the production of nice flowers. Lifted plants, so treated, are very beautiful and useful.

The Single-Flowered Varieties.—Unlike the late-flowered Japanese, the singles bear beautiful blooms on late growths, that is, shoots that grow after the middle of August. The flowers are of good form, of fair size and very rich in colour, and, furthermore, from three to five blooms can be obtained from each main stem, as they grow so freely after a crown bud has formed and been pinched out. Cultivators who are growing the single-flowered varieties for the first time this year need not be over-anxious as to the flowering of the plants; the blooms will not be unduly late, as the buds open so quickly. Nearly all the plants of this section grow more than 4 feet high.

When blooming on terminal shoots they generally average 5 feet in height, so that space for them under glass should be got ready accordingly.

Suckers.—These, too, are growing rapidly, and they are stronger and more numerous on the singles than any others, unless it be the border varieties. Remove them while they are small and without damaging or even disturbing the main roots of the plants in the surface soil.

Feeding.—During dull and wet weather give artificial manures (not liquid manure) in small doses and not too frequently. By so doing the judicious feeding of the plants can be continued even while it is unwise to apply stimulants in liquid

A SPRAY OF THE LITTLE KNOWN SHRUB
PLAGIANTHUS LYALLI.

form. Mix the artificial manures with finely sifted rich loam, and put on the mixture in very thin layers and frequently—twice a week at this stage.

Hardening the Stems.—The plants at this stage cannot be exposed too much to the sun and air, because they grow so rapidly, and when once they are placed under glass the new wood does not harden very much; this must be done in the open air.

Plants with Forward Buds.—Some of the Japanese varieties are rather forward and must be duly protected. The blooms are not improved,

but marred, if the petals which are now showing colour are exposed to the dews or to rain. Make preparations for placing the plants in a cool, well-ventilated greenhouse, conservatory or Peach-house at once. The blooms will be fully developed by the third week in October, and will be useful in a cut state for tall vases when outdoor flowers are becoming scarce, as well as for prolonging the display of blossom in the greenhouse. Feed these plants liberally. AVON.

IXIAS AND SPARAXIS.

THE merits of these pretty South African bulbous plants for the embellishment of the greenhouse are too frequently overlooked. A group of flowering examples during the latter part of the spring is sure to arrest attention, first, for their splendid display of bright-coloured blossoms, and, secondly, from their distinct character. There is nothing in the greenhouse at that time which is at all likely to be confounded with them. My reason for referring to them now is that no time should be lost in potting them up, as the bulbs are small and will quickly lose some of their vitality if kept stored in paper bags in a warehouse. The most suitable compost for both *Ixias* and *Sparaxis* is loam, lightened, according to its consistency, by sand and well-decayed leaf-mould. Good examples may be grown in 5-inch pots, putting six to eight bulbs in each pot. The bulb should be buried at such a depth that the top portion is about three-quarters of an inch below the surface of the soil. After being potted they may be placed in a frame where they are safe from frost, or in a greenhouse from which frost is just excluded, but nothing more. Very little water will be needed till signs of growth appear, after which the supply must be increased. These pretty flowers, with their thin yet firm stems, are very useful for many purposes in a cut state. H. P.

WHAU-WHI OR LACE BARK.

(*PLAGIANTHUS LYALLI*.)

Now is the best time to increase this lovely subject. It is, to my mind, one of the best of summer-flowering shrubs. The beautiful clusters of pure white flowers, which are produced in July, are separately borne upon a stalk about 1½ inches in length. Not only is it free flowering, but another of its merits is its lasting power. The shrub itself has rather a spreading habit. The cuttings should be of this year's wood, about 3 inches to 4 inches long. Prepare a pot (about 5 inches) with sandy loam, making it very firm. Be certain that the drainage is perfect. Prepare cuttings in the usual way and dibble them in with a pointed stick, being very careful to make the soil firm round the base of each. Water the cuttings in and plunge them in a frame of Coconut fibre with a little bottom-heat. It may also be increased by layering, and this is quite a ready means of propagation. Travellers tell us that this is one of the most beautiful trees of the New Zealand flora. It is hardy in the London district, but in the colder parts of the country it should be planted against a wall. The year 1871 is given as the date of its introduction from New Zealand, where it is popularly known as the Lace Bark. A. A.

NOTES ON VEGETABLES.

Celery.—The early batch should have its last watering, thoroughly saturating the roots with liquid manure to increase the size of the sticks, especially if they are required for exhibition, and placing another fold of brown paper on the top, if required, tying it round tightly to make the blanching secure. The late batch to be blanched with soil and kept for winter and spring use should be well watered before earthing, assuming it has not been earthed before. Dust the sides of the trench and the plants with soot to prevent slug attacks, which disfigure so many of the outer leaves.

Cauliflowers and Early Broccoli just forming heads may be much assisted by occasional doses of liquid manure; or, if the ground is mulched, clear water would suffice. Heads that are grown quickly by giving copious root waterings during dry weather are much more succulent and tender than those that take so long to grow during dry weather. Plants intended for putting out early in spring should now be pricked out in frames and kept close for a few days until root action has again started, when the lights should be removed to induce a stocky growth, only replacing them when frost appears likely to occur.

Cardoons.—Continue the blanching of these as growth progresses, being careful to wind the hay-bands closely around the stems and keeping the paper underneath firm.

Rhubarb.—A root should now be lifted carefully, placing it in the Mushroom-house or in any warm, dark structure, covering it to exclude light. Keep the soil moist, encouraging the growth to come away steadily.

Mushrooms.—Continue to collect and prepare material for the beds. Freshly gathered horse-manure, with a fair quantity of short straw, is the best material to use, although for economy a few freshly gathered leaves will add to the bulk where horse-manure is not easily obtained. When a sufficient quantity has been collected for a flat bed 18 inches deep, or a ridge bed 3 feet high, and as much in diameter at the base, throw it into a heap and encourage it to ferment by adding water if the material is too dry, and thus get rid of the obnoxious gases.

Radishes.—Make thin sowings in frames in light, sandy soil. As the seedlings appear, protect the tender growth by covering the glass at night in case of frost. Any late crops outside should have similar protection to ensure completion of growth.

Tomatoes.—Very variable are the results of open-air culture this season. In some localities the wet and cold weather of July quite ruined the prospect of a crop, the plants collapsing by disease of the stems near the surface towards the end of August, at a time when they were nicely set with fruit. This fact emphasises the advantage of having fully grown plants when put out at the end of May. In some drier localities the outdoor crops have been a success. Sunrise and Holmes' Supreme, as usual, have done the best. Any fruit now changing colour should be cut and

placed in a dry, warm room to finish ripening. Plants under glass must not be over-watered nor too freely fed. A steady growth, without too much excitement either by heat or strong stimulants, will be the best conditions in the end. Small plants intended for next year's early crop should be placed near the glass in a temperature of not less than 60° by night to ensure a stocky growth. Do not over-pot them for winter growth; neither should they have too much moisture.

Parsley.—In some gardens a difficulty is experienced in keeping the plants in a healthy growing condition throughout the winter, some constituent in the soil being unsuitable. To obviate this and to ensure a stock, plants raised from seed sown in spring should be lifted and placed in frames of prepared soil consisting largely of charred loam, leaf-mould, wood-ashes and soot, with some sharp sand. Keep the lights somewhat

it is the result of a cross between a Blackberry and a Raspberry, but some are inclined to think that it is a true natural species. However that may be, it is one of the few useful fruits for which we have to thank our American cousins.

It is an exceedingly vigorous subject, frequently making growths 12 feet or more long in one season, hence it must be given plenty of head-room. A favourite situation for it is over an arch, where it forms a beautiful and at the same time useful plant. It delights in a deeply worked, rich and rather heavy loam, which will afford it a cool root-run during the hot days of summer. After the fruits are gathered, the growths which have borne them are cut right out at the base, the best of the young ones being tied in to take their place and for bearing fruit the following year.

As will be seen by the illustration, the fruits are freely produced in large lusters, and they

THE LOGANBERRY. THIS FRUIT SHOULD BE GROWN IN EVERY GARDEN.

close for a few days until new roots are forming; then give abundance of air, finally drawing off the lights in favourable weather to ensure stocky growth.

Lettuce.—Fill the spare lights with plants 6 inches apart where they are intended to heart for autumn use. Where the plants are small, dibble them thickly in frames to ensure a stock for early planting by thinnings, leaving the stronger ones to mature early in the frames.

Swanmore.

E. MOLYNEUX.

THE LOGANBERRY.

With the advent of many new hybrid berries of the Bramble section, the merits of the Loganberry are apt to be overlooked, yet it is a most useful fruit and should find a place in every garden where a fair amount of room exists. Reputedly

much resemble large Raspberries in shape and size, being red in colour when ripe. Owing to a rather acid flavour, they are valued more for preserves than for dessert, although when thoroughly ripened they are very nice.

Propagation is easily effected by pegging down the tips of the young, non-fruiting canes and covering them with soil. Treated thus, they quickly form roots, when they may be severed from the old plants in the autumn, and either grown for one season in a nursery bed or transferred direct to their permanent positions. As planting-time will soon be here, those who have room and suitable soil for a plant should make a point of securing one. Naturally, such a fruit has quickly been made good use of by hybridists, the Lowberry and the Laxtonberry being two good fruits obtained by using it as a parent.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Melons.—At this time of year sunshine may not be so plentiful as one might desire to mature Melons perfectly. Therefore more care is necessary in the management of the plants. Less atmospheric moisture will be necessary than formerly, and a little heat must always be maintained in the pipes. The roots must not be overwatered, especially when the fruits commence to colour.

Plants Under Glass.

Dielytra spectabilis.—Clumps of this useful greenhouse plant may now be potted. Pot them into 7-inch or 8-inch pots, and plunge the pots in ashes out of doors till growth commences. They may then be placed in a cool house.

Azalea indica.—It will not be safe to leave the plants of this any longer outdoors. Before placing them under glass, lay them on their sides and give them a thorough syringing with an insecticide as a precaution against red spider. A house where they can have abundance of air will suit them till they are required for forcing.

Chrysanthemums.—Some varieties of the decorative kinds will need disbudding, and this work must not be delayed when the buds are large enough. The plants must not be neglected in the matter of watering, and stimulants should be afforded till the blooms are well advanced. The houses where the large blooms are expanding must be kept as dry as possible, or the petals will damp.

Calanthes.—The useful *Calanthe Veitchii* is now finishing its growth, and in order to ripen the bulbs perfectly, give them plenty of room so that all the light possible may reach the bulbs. A good circulation of air, combined with a brisk heat in the pipes, will create suitable atmospheric conditions. Keep the roots well supplied with water till the foliage begins to die down.

The Flower Garden.

Wintering Bedding Plants.—The housing of large bedding plants requires very careful forethought where glass accommodation is on a limited scale. In most gardens, fruit-houses which have been cleared of their crops have to be made use of for this purpose. Plants which have to be dug up and repotted should be first placed in a warm, moist house for a week or so, and kept shaded till they have recovered from the check. They may then be placed in a vinery or Peach-house for the winter. *Hydrangea hortensis*, *Cannas* and *Fuchsias* may be stored in a frost-proof shed. Sweet *Verbenas* may be given similar treatment. Here we have several very large specimens which are wintered in a barn. Tuberous-rooted *Begonias* should be lifted and placed in a frame till the foliage has died down; they must then be placed in boxes and stored in a frost-proof shed. *Echeveria secunda glauca* may be planted closely together in a cold frame. *Lobelia cardinalis* may be lifted and placed closely together in boxes, covering the roots with soil. They will be safe in cold frames, providing the glass is covered with mats during very severe frost.

Sweet Peas.—If autumn sowing is contemplated, it should be done as soon as the condition of the ground will allow. The seed should be sown in shallow trenches. If the ground is inclined to be heavy, a little old potting soil will be of considerable benefit. Mice must be guarded against by setting traps along the rows, and as soon as the seedlings are through the soil, strands of black cotton placed over the rows will keep off birds.

The Hardy Fruit Garden.

Figs.—If the weather continues favourable, the fruits will still ripen, providing the trees are not congested with growth. If the growth is too crowded, it should be liberally thinned, as this will also facilitate the ripening of the wood.

Peaches and Nectarines.—When all the fruits have been gathered, all the old fruiting wood may be removed so that that required for next year may have every chance to become thoroughly matured. Give the trees a thorough drenching with an insecticide, and should the roots need water, give

them a soaking with the hose-pipe. Young trees which are inclined to be too strong must be lifted and replanted, using plenty of old brick rubble in the process.

Planting Fruit Trees.—The new stations may now be prepared for the planting of young trees, as this will greatly facilitate the work when the trees arrive from the nursery. Be careful in the selection of varieties, for much disappointment may easily be caused by neglect in this matter. The lifting and root pruning of young trees may be proceeded with now. Most of this work should be done before the turn of the year.

The Kitchen Garden.

Onions.—Take advantage of a wet day to look over the main stock of Onions and remove those which are blemished. These may be put aside for immediate use. The method of roping Onions for long keeping is a good one, as not only do they keep better, but when hung over the roof of a shed the decayed bulbs may easily be detected. Autumn-sown Onions will now be sufficiently advanced to permit of the hoe being run between the rows. Light dustings of soot will be beneficial prior to hoeing.

Tomatoes.—The winter-fruiting plants will now be setting their fruits, and during dull, sunless weather it may be necessary to keep a little heat in the pipes continuously. Admit plenty of air on all favourable occasions and keep the atmosphere dry. A little fresh material placed over the roots occasionally will considerably enhance the swelling of the fruits.

Chicory.—If suitable roots are available, a few may be introduced to the forcing-house. The roots may be planted in large pots or boxes and covered to exclude light.

Mustard and Cress.—A supply of this useful salad may be kept up by sowing frequently in boxes. It is better to make small sowings frequently than to sow large quantities at one time, which often results in a great deal of wastage.

E. HARRISS.

(Head-gardener to Lady Wantage.)
Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Flower Garden.

Sweet Peas.—Seeds should be sown in small pots as soon as they can be got, it being generally admitted that finer plants of most varieties result from autumn sowing. If, however, they cannot be sown before the first week in November, they are better left over till January, when they germinate more strongly. Sweet Peas at no time should be subjected to strong heat; in fact, if they are simply kept from being frozen it will suit them, but ample ventilation is essential together with careful watering.

Roses.—Many of the strong-growing varieties, having made long growths, are likely to become loosened at the neck by wind and thereby injured. The longest shoots should be shortened, and the plants made firm to prevent breakages. As the planting season is at hand, lists with notes should be made in readiness.

The Kitchen Garden.

Celery.—The second earthing-up of the main crop must be proceeded with. Care should be taken that the leaf-stalks are kept close together while this is being done, to prevent any soil getting between. If possible, attend to this when the soil is in good working condition.

Cauliflower which was sown early in September should now be pricked out in cold frames 4 inches or 5 inches apart. As slugs are very partial to the young leaves of this vegetable, the latter should be dusted with soot immediately. Keep the lights closed for a few days; afterwards grow as hardily as possible to better withstand the winter.

Spinach.—The late-sown plants should be thinned out, at the same time removing all weeds, which would not perhaps seed during winter, but would impoverish the soil and make it present an untidy appearance. Use the hoe when the soil is sufficiently dry.

Watercress.—Where the grower has not the convenience of a running stream, quite good supplies can be obtained from frames during winter. Plants from seed sown during August are now ready for pricking out in frames. Protection from frost is necessary.

Endive may still be pricked out in frames, allowing a distance of 6 inches between the plants. As the season is not now conducive to a quick growth, less ventilation should be given to encourage more rapid progress.

Fruit Under Glass.

Melons.—Any fruit still remaining in frames will be better cut and kept in a light and warm glasshouse in the full exposure of the sun, where it will have a better chance of ripening. Melons growing indoors must be watered carefully at this season, or the flavour will be ruined. Maintain a minimum temperature of 65° at night and do not spill water on the floors.

Late Vineries.—Where the Grapes are not colouring satisfactorily, help must be given by artificial means. Keep a brisk heat in the pipes constantly, with air on the ventilators top and bottom sufficient to keep the atmosphere in a fresh condition. Bad berries must be looked for and removed at once, avoiding touching any of the surrounding berries.

Midseason Grapes which may still be left hanging will be much better cut and bottled, as not only do they tax the Vines needlessly while left hanging, but they lose colour and, in most cases, shrivel.

The Hardy Fruit Garden.

Fruit Gathering.—A great number of Apples and Pears are ready for pulling, and should not be left to fall. It is well, however, to go over each tree more than once, as all the fruits may not be quite ripe at one time. Preference of space in the fruit-room should be given to late varieties requiring to be kept until spring. Early sorts may be stored in greater bulk, seeing they are to be used so soon. On no account should fruit be pulled before it parts readily from the tree, otherwise shrivelling is certain to take place along with impaired flavour. The ideal fruit-room for storing Apples is under ground or in the shade, and not one which dries up quickly. Pears keep better in a freely ventilated building, which should be dry but not too warm.

Plants Under Glass.

Humea elegans.—The young plants should now be shifted into 5-inch or 6-inch pots, in which they will remain until spring. Use a good compost with sufficient charcoal and grit to keep it porous. This plant quickly shows the bad effects of careless watering, therefore discretion must be used when applying water. Keep the plants in a cool, well-ventilated pit to encourage a sturdy growth.

Tuberous Begonias, now having passed out of bloom, must be given slightly drier treatment, gradually withholding water altogether when the foliage has ripened. Afterwards they can either be laid on their sides in the pots or, if space is not plentiful, shaken out of the soil and stored in a fairly dry shed in boxes covered with Coconut fibre.

Forcing Bulbs.—The early kinds, such as Roman Hyacinths and Paper-White Narcissus, being late in reaching this country during the past summer, they naturally are not so well rooted as they otherwise would have been at this period. It is always better to make certain there are sufficient roots before introducing the bulbs into heat, which should not be too brisk at first.

Malmaisons.—Young plants of varieties with such good habits as Princess of Wales and Duchess of Westminster, which can be flowered successfully during winter, should be shifted into 6-inch pots as soon as they are sufficiently rooted. The compost used must contain a large proportion of broken brick or tiles, charcoal, crushed oyster shell, leaf-mould and silver sand. The loam used must be very fibrous. After potting, water with caution and keep cool, not, however, allowing the temperature to drop below 50°.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS

TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

NEPETA MUSSINII (E. F. C.).—If the plants have outgrown their station, they may be cut back with impunity to quite near their bases. Then, if need be, when they have broken into fresh growth you may lift and divide, or defer the operation till spring. In some soils and districts growth is so abundant that shearing is resorted to annually, though this is not necessary where bold effect is desired, or in those instances where the fuller grey tone of the plant is most appreciated. This is usually attained by two year old plants on the let-alone principle, and in a rather poor soil.

PROPAGATING DOUBLE-FLOWED GYPSOPHILA (F. Norman).—On its own roots the above may be propagated from root cuttings inserted in January, inch-long pieces being sufficient with a greenhouse temperature of 55°. Grafted plants would probably give you nothing more than the stock on which they were worked, unless the plant had subsequently rooted on its own account, and roots from this were taken with the rest. It may, however, be increased by means of cuttings, those preferably secured with a heel from about the base of the plant when about 3 inches long. Such cuttings are not numerous produced, though their numbers may be increased by cutting back the earliest-formed shoots, which causes them to break again.

TREE CARNATIONS (M. Robertson).—The Tree Carnations that flowered last winter and are still in their pots are not likely to do you much further service, and would be best discarded in favour of young plants. Those you put out of doors may, if top-dressed or given liquid manure, do somewhat better, though everything depends upon how they have been treated; and if there are no signs of flowering shoots this month, it is hardly likely that any will be formed later. These plants are best raised annually from cuttings inserted in January and well cultivated throughout the year. Your question, "Ought Cacti to be repotted which have not been touched for years?" must be answered in the affirmative. The time, however, is not now, and May would be much more suitable. It is difficult to know what they are from your description, though we imagine the white, sweet-scented one to be one of the *Phyllocacti*. The best soil mixture for these plants is one composed of loam and old mortar or brick rubble screenings in about equal parts. To these add a little sand, leaf-soil or peat. They require careful handling at such times, perfect drainage, moderate supplies of water during growth, and little or none during the greater part of the winter.

LILY OF THE VALLEY (FORTIN'S) FOR OUTDOORS (A. W.).—The Lily of the Valley in all its forms delights in rich vegetable soils, cool, partially shaded positions, and revels in abundant moisture. A dry, sunny border would therefore be the worst possible place for the plants. In the wild state the plant frequently inhabits dry, shady woods, but in such the growth and flower-spike is short. In the richer soils referred to, stature, length of flower-spike and size of flower are all increased.

Therefore dig or trench the so deeply and add well-decayed manure and leaf-mould liberally. In planting keep the crowns well out of sight, and arrange them singly 6 inches asunder in rows about 9 inches apart. Thus treated, a bed with annual mulching and liquid manure would be good for years. The finest development of this plant we have ever seen was in a Thames-side garden, where, in addition to the above treatment, the ground was occasionally flooded for short periods in winter time. The position was moderately sheltered, though suffering much from fog and damp by reason of the close proximity of the river. In your case the selection of a rather sheltered spot would be desirable.

LILIUM AURATUM FAILING (M. F. C.).—The defective or deformed buds are primarily the result of root inactivity, and, in all probability, if you examine the bulbs you would find the basal roots deficient in numbers or in some instances quite absent. It is largely due to the drastic measures employed in Japan prior to the bulbs being packed for shipment to this country, and which includes denuding the bulbs of their existing roots. Subsequently, for a year, they have to depend for their existence on the stem roots and the meagre supplies which are issued from the base of the bulbs, and their future depends upon these being many or few. Usually the variety *platyphyllum* is better behaved because of a more vigorous root action. Otherwise the cultivator in this country is well-nigh helpless. The only way to destroy the fungus would be by digging out and burning it and the affected soil area, or you may bury it in a deep pit and cover with gas-lime or apply weed killer. These, of course, cannot be employed among the shrubs, though a heavy liming of the soil in addition to digging out and burning the affected areas might also prove of service.

LILIES (H. F. Sykes).—The vast majority of Lilies are hardy enough and few require to be lifted each year; the chief trouble is to establish them in suitable soil. You say nothing about your garden, whether it is in sun or shade, and not a few species are benefited by protection from late spring frosts. This is best done by planting them in groups among low-growing shrubs, though this is not essential in a garden moderately well sheltered. The following are both hardy, robust of constitution, and well suited to your garden soil as it exists or with the addition of a third of leaf-mould and sharp grit. Well-drained, well-cultivated soil is essential to all. *L. candidum*, the white Madonna Lily, should have a dry, rather sunny spot in not over-rich soil. *L. croceum*, *L. excelsum*, *L. Martagon*, *L. M. album*, *L. chalcedonicum*, *L. pyrenaicum*, *L. pomponium verum*, *L. umbellatum* *Diadem*, *L. u. grandiflorum*, *L. u. incomparabile*, **L. colchicum*, *L. bulbiferum*, *L. pardalinum*, **L. Hansoni*, the last two preferring a little peat or plenty of leaf-soil with the staple, and a position sheltered from hot sun. To these may be added **L. Henryi*, **L. speciosum rubrum* and *cruentum*, **L. s. Melpomene* and **L. s. Krætzleri*, all of which, in addition to being planted 6 inches deep, should have a little well-decayed manure incorporated with the lower soil. *L. tigrinum Fortunei*, *L. t. splendens*, and *L. t. flore pleno* should have light, freely drained soil, while **L. auratum platyphyllum*, one of the most noble of Lilies, will repay for a special bed of loam, leaf-mould and grit in about equal parts. It should be planted 6 inches deep at least in a sheltered place, the bulbs well surrounded by sand. The Madonna Lily should be planted immediately, the remainder as early as possible. The best display would follow planting in groups of three or six bulbs to each group. Those marked by an asterisk should have a mound of ashes or Coconut fibre placed over their stations for the first winter to throw off excessive wet. The selection given are in flower from late in May to the end of September or later.

TREES AND SHRUBS.

EVERGREEN CLIMBING PLANT FOR WALL WITH NORTHERLY ASPECT (E. T. M.).—There is nothing better for a wall with a northerly aspect than some of the small-leaved kinds of Ivy, like *Hedera Helix* var. *donerailensis*, or forms of *H. H. marginata*, which have red or golden margins to the leaves.

COPPER-LEAVED PLUM FRUITING (Huntly).—The Copper-leaved Plum (*Prunus cerasifera atropurpurea*, or *P. Pissardii* as it is often called) has fruited in numerous places this year. It is not an uncommon event for it to produce fruits, but it rarely bears a good crop in this country, probably by reason of its early flowering, cold weather being against the fertilisation of the flowers.

TREATMENT OF MUEHLENBECKIA (H. G. G.).—You cannot do better than cut your plant of *Muehlenbeckia* back below the point where the branches have become twisted or bent over. It is not really necessary to cut it back to the ground line, and it is probable that it would start into growth again better if not cut into very old wood. Any growth that is in the way may be removed now, but the more severe pruning had better be left until March or early April.

BLEACHING HEATHER (A. B. W.).—We know nothing of bleaching these plants, but such as the white Scotch Heather, *Erica cinerea alba*, and the white-flowered forms of the Ling, *Calluna (Erica) vulgaris*, should at least require no such treatment, since the flowers remain effective for weeks, often months. The best of these varieties are *alba*, *Serlei* and *Hammondii*, and of late years a considerable trade has been done in them for cutting for the Scottish and other markets.

HIBISCUS SYRIACUS (A. B. H.).—This cannot generally be considered a success in Scotland, though in some South and West Scotland districts it grows well and flowers annually. In some other gardens in those

districts, however, it either flowers irregularly or does not bloom at all. It does not flower in the North of England. We know it has been tried in two South of Scotland gardens for years, but has never produced a flower. It is a plant requiring a mild climate and a sunny position. Even then it is not reliable in Scotland.

FLOWERING SHRUBS FOR COLOUR AND EFFECT (Veronica).—The following shrubs are likely to suit your purpose: *Spiraea arguta*, 3 feet to 4 feet, white, April; *Philadelphus Lemoini erectus*, 2½ feet to 4 feet, white, should be pruned hard after flowering in June; *Cytisus praecox*, 3 feet to 4 feet, cream, May; *Spiraea japonica* var. *Anthony Waterer*, 1½ feet to 2 feet, red, summer; *Diervilla Eva Rathke*, 3 feet, red, June to August; *Ceanothus Gloire de Versailles*, 3 feet, blue, July to October; *Veronica speciosa*, 2 feet to 4 feet, flowers blue, red or white, autumn and winter; *Forsythia intermedia densiflora*, 4 feet, yellow, April; *Cydonia Maulei superba*, 2 feet to 2½ feet, red, May and June; *Escallonia philippiana*, 3 feet to 4 feet, white, July. The following Liliiums may be grown: *Henryi*, *candidum*, *pardalinum*, *bulbiferum*, *chalcedonicum*, *auratum*, *croceum*, *Hansoni*, *Martagon*, *szovitzianum*, *pyrenaicum* and *speciosum*.

AZALEAS FAILING (T. Q.).—It is impossible to state definitely the reason of your Azaleas behaving in the way they have done. Several suggestions might be made, and each wide of the mark. One thing which is very apparent is that the sprays from the three other plants show that there has been nothing wrong in their treatment. It is more than probable that the roots of the unhealthy plants are in a bad state, and the trouble may have started some time before they came under your care. Then the change into the mansion, if only for a few days, would, with the dry atmosphere to which the plants were there subjected, inflict a strain on them. A succession of very heavy rains after they were stood out of doors would then tend to finish matters. If you examine the roots, we expect you will find that the greater part of them are dead. You speak of the plants being quite dwarf. Is it possible that two plants were put together when very young, and after growing up together for so long, one of them has at last died? We are sorry that we cannot give a more decided answer, but, as above stated, we think the trouble commenced some time before you took charge. The slight yellow marks noticed by you when you came would indicate an unhealthy condition of the roots.

ROSE GARDEN.

ROSE E. VEYRAT HERMANOS (Thos. H. Smith).—We have this Rose growing in the aspect you name, N.N.W., and it blooms well. We should advise well preparing the border, and, if possible, training the growths out laterally, as the variety is rather a shy bloomer, and this induces blooming.

PRUNING WEEPING ROSES (O. G. P.).—It would have been best had the trees been pruned soon after flowering in July. The growths that have flowered should be removed, or at least most of them. This will give the new growths a better chance of developing. But it is not too late to do the work now. Do not cut away any of the young growths. You might pinch out the points of the youngest of them in October. This would help them to harden for the winter.

DOROTHY PERKINS AND ITS WHITE SPORT (Chas. Comfort).—This Rose is very sportive, and probably the reason you have two shades of the pink form is that the plants were derived from cuttings. Possibly the different positions in which the plants are grown would also account for this. As to the white variety, that known as *Cant's White* is the purest, but even this is liable to throw off pinkish sprays. The flesh-tinted spray sent may in time revert to the pure white. We have budded from such sprays, only to find the next year the plants gave pure white clusters. Lady Godiva was a sport of Dorothy Perkins. We have also seen both white and pink clusters on the same plant of Dorothy Perkins.

CLIMBING ROSES WITH EXHIBITION BLOOMS (Pro Rosa).—There are several grand Roses quite suitable for your purpose, and we can thoroughly recommend those named below for your arches. No. 1.—Climbing Caroline Testout and Climbing Lady Ashtown. No. 2.—Climbing Mélanie Soupert and Climbing Paul Ledé. No. 3.—Hugh Dickson and J. B. Clark. No. 4.—Climbing White Maman Cochet and Climbing Kaiserin Augusta Victoria. No. 5.—Climbing Mrs. W. J. Grant and Climbing Richmond. No. 6.—Mrs. Stewart Clark and Mme. Jules Gravereaux. Should you desire other sorts, we can recommend Annie Crawford, Mme. Wagram, Frau Karl Druschki, Candeur Lyonnaise, Coronation (Hybrid Perpetual) and Heinrich Munch. These climbing sports of well-known varieties should not be cut back hard the first year. Allow at least 4 feet to 5 feet of their growths to remain. Later on, when well established, you can cut away the old wood and retain the new growths almost their full length. Be careful to plant in deeply dug, well-manured soil, and do not forget to water liberally with liquid manure during early summer.

ROSE FOLIAGE SPOTTED AND DISEASED (L. Knox).—The plants are attacked by the black spot fungus and also red rust. It is useless to spray now, but we advise you to gather up all the foliage that has fallen and burn it; then in November transplant the Roses either to a new position or to their present site, taking care to well trench the land in either case. Before removing the plants it will be well to take away the surface soil to a depth of about 2 inches and burn it, as the resting spores of the fungus will abound in the surface soil. When removing the plants, cut this season's growths back to about 6 inches and remove all the foliage. You can then prune in the

ordinary way next spring. Early next summer spray the plants with Bordeaux mixture, and do this throughout the season at intervals of about ten days. Probably you have a lot of the old Hybrid Perpetual Roses, which are particularly susceptible to red rust and black spot; if so, discard them for the more desirable Hybrid Teas.

FRUIT GARDEN.

FIG TREE DROPPING ITS FRUIT (*Miss Sykes*).—The fruit (on the sample branch sent) is on the shoot of this year's growth (what is commonly termed the second crop). This second crop ripens very well on trees growing under glass, but never on trees growing out of doors. The fruit which ripens out of doors is always borne on the shoots of last year's growth and should be ripe now.

INSECT ON PEAR LEAVES (*E. C.*).—The insect on the Pear leaf sent is the Pear slugworm. It feeds also on Cherry, and is the grub of a sawfly. The sawfly is a small four-winged fly which lays its eggs on the leaves of Pear or Cherry, and, as you have seen, the larvae feed on the upper surface of the leaves. Later they become very dark green, almost black, and when they have eaten all they can, fall to the ground, where they bury themselves through the winter, the first brood of flies appearing about June. The best means of dealing with them is to dust the foliage with powdered lime. This adheres to the insect's coat, which it endeavours to change. Dusting again within two days makes it want to change its coat again, but it is unable to do so and dies. The removal of the top 3 inches or 4 inches of soil during winter would also be a good measure, for it would enable you to burn or bury the larvae very deeply.

PEACHES DECAYING (*H. H.*).—The Peach was rotten when received, and therefore served no useful purpose in giving a clue as to the cause of its decay. However, we gather from your letter that the cause of the trouble has been stone splitting or decay, which is the same thing. Judging by the enquiries we have had, this complaint has been general this year. We have no certain and exact knowledge as to what is the cause of this disease. Some attribute it to ants finding their way to the stones through an opening at the base of the stalk of the fruit and thus causing the mischief. Others contend that the disease is due to defective fertilisation of the flowers at the time they are open. We believe this to be the true cause. Next year be careful to fertilise the flowers artificially by impregnating the stigma or centre column of the flower with the pollen of some other variety in bloom at the time. The best way of doing this is by rubbing a rabbit's tail over the pollen, and then applying it to the end of the stigma of the flower you wish to fertilise. This should be done about noon on a fine day when the pollen is dry.

MISCELLANEOUS.

ANTIRRHINUM FOLIAGE DISEASED (*Miss R. E.*).—We fear you will continue to have trouble with the bed of which you speak, as it seems thoroughly infested with the fungus *Botrytis*, which has attacked your Lilies, your Tulips, and apparently also the Antirrhinums. This fungus in its various forms is very frequent, especially in richly manured soil deficient in lime, and probably also deficient in potash. Possibly the bed is somewhat exposed. We think your best plan would be to remove all the soil from it and replace with fresh, mixed with chalk, and see also that the drainage is of the best. Probably the addition of wood-ashes would also be an advantage. It is hardly likely the Antirrhinums will recover, but if you could take cuttings of healthy shoots about the beginning of October, there might be a chance of keeping them healthy in different soil.

ROSE SOIL (*R. F. C.*).—Your soil needs enriching with good organic manure, such as cow-manure. We advise you to have the beds well trenched, and work in liberally good, well-rotted cow or pig manure with the lower spit of soil. You cannot well give too much of such manure if you take care it is put well down, say, at least 18 inches from the surface. This would form a nice cool medium for the roots when they reach it next summer. At the same time work into this lower soil some basic slag, at the rate of 6oz. to the square yard. If you can obtain some well-decayed hot-bed manure, you might incorporate a moderate amount of this to the upper 18 inches, well mixing it as the trenching proceeds. We advise you to make a heap of all lawn edgings and old potting soil, and throw on this during the winter any liquid manure you can collect. This would make fine material to spread on the beds in May. A soil such as yours needs enriching as suggested in order to grow good quality Roses. You must take care to plant very firmly, and see that the roots are pressed again after the plants have been set in position a week or so. If you are in a position to obtain spent hops, these could be added to the heap of mixture mentioned above with considerable advantage, and would make an excellent mulch for summer use.

HOW TO INCREASE TULIPS AND LIFTING LILIES (*Mrs. Glossop*).—Grade your Tulips into three sizes. Plant all the large ones (such as you would expect to buy from a dealer) in places where you want flowers for garden decoration. Then plant the second size in beds in the kitchen garden or elsewhere, so that they can be used for cutting, as some of them will not bloom. These should be put in before the end of September. The third—top of your thumb—size plant at once 1½ inches deep and 1 inch between the little bulbs, in beds. A few will bring quite small flowers, but

the majority will not flower. To ensure these mites being put in properly, it is best to make the bed or beds the desired size, and then to throw the soil out before planting. In this third size the rows should be 3 inches apart. These should be put into the ground as soon as possible. With regard to your Lilies, much depends on the nature of the soil. If light and well drained, all three might do very well without lifting, but it is doubtful if longiflorum would be hardy with you, so it would be best to lift and replant. If the Lilies are planted among shrubs, it is, of course, a great protection.

NAMES OF FRUIT.—*P. P.*—1 and 12, Lady Henniker; 2, Cobham Pippin; 3, Easter Beurré; 4, Beurré Diel; 5, Keswick Codlin; 6, Williams' Bon Chrétien; 7, Wellington; 8, Warner's King; 9, Beurré Clairgeau; 10, deformed fruit, cannot recognise; 11, Glou Morceau; 13, New Hawthornden; 14, Blenheim Orange; 15, Lord Grosvenor; 16, Yorkshire Beauty; 17, Marguerite Marillat; 18, Windsor Pear; 19, Beurré Superfin; 20, Beurré Goubault. —*F. W.*—1 and 4, Marie Louise d'Uccle; 2, Pitmaston Duchess; 3, Doyenné Boussoch. —*Miss Holmes*.—1, Mank's Codlin; 2, Bramley's Seedling; 3 and 4, not recognised; 5 and 6, Ribston Pippin; 7, Lord Derby; 8, Golden Noble; 9, Sheep's Snout; 10, not recognised; 11, Worcester Pearmain. —*A. T. U.*—*Reigate*.—1, Williams' Bon Chrétien; 2, Swan's Egg; 3, Emile d'Heyst; 4 and 5, Trout Pear; 6, Broom Park; 7, New Hawthornden; 8, Caillot Rosat; 9, Lord Suffield. —*Elizabeth*.—1, Thorne Pippin; 2, Kerry Pippin; 3, Mank's Codlin; 4, Annie Elizabeth; 5, Hawthornden Pippin; 6, Bismarck. —*A. H.*—1, King of the Pippins; 2, Hawthornden; 3, Golden Spire; 4, Emperor Alexander; 5, The Queen; 6, Mank's Codlin. —*W. P. L.*—Cox's Orange Pippin.

NAMES OF PLANTS.—*Fan*.—*Magnolia acuminata*. —*H. G. S.*—*Brasted*.—In gardens and nurseries grown as *Rubus fruticosus* flore roseo pleno; the botanical name is *Rubus ulmifolius* flore pleno. —*Mrs. Hart*.—Roses: 1, Papa Gontier; 3, Lady Ashtown; 4, Lady Battersea; 5, Enchantress; 6, Mme. Lambert; 7, Countess of Gosford; 8, Admiral Dewey; 9, Souvenir de Pierre Notting; 12, Marie van Houtte. The Roses had travelled very badly, and most of them were too far advanced when cut. —*S. R. H.*—*Cork*.—1, *Campanula lactiflora*; 2, *C. lipifolia* variety; 3, *Lotus corniculatus*; 4, cannot identify, too scrappy; 5, *Aster acris*. We are not acquainted with an Encrusted Saxifrage named Top-Saver. —*Curious*.—1, *Eupatorium purpureum*; 2, *Helenium autumnale cupreum*. —*T. C. Crackers*.—1, *Taxodium distichum*; 2, *Tsuga canadensis*.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

The fortnightly meeting of this society was held at Vincent Square, Westminster, on September 28. Vegetables, both competitive and non-competitive, formed the chief feature of the exhibition, while hardy flowers were shown in great profusion.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. C. T. Drury, E. A. Bowles, G. Harrow, R. C. Notcutt, J. Green, J. W. Barr, W. J. Bean, R. W. Wallace, G. Reuthe, J. W. Moorman, J. F. McLeod, W. Howe, T. Stevenson, W. Bain, C. Dixon, A. Turner, H. J. Jones, C. E. Shea, C. E. Pearson, W. P. Thomson, E. H. Jenkins, C. R. Fielder, J. Dickson, G. Paul and W. Cuthbertson.

Nothing was more finely shown or effectively displayed than the magnificent grouping of *Ixoras* from Lady Nunburnholme, Watter Priory, York (gardener, Mr. F. Jordan), the excellent group at once a credit to cultural skill and to a phase of indoor gardening not too frequently seen. The group was of one kind—*I. coccinea*, which for freedom of flowering and rich colouring is not easily surpassed. Arranged with Palms, Crotons, Ferns and other ornamental foliage, this constituted a great attraction.

Messrs. Barr and Sons, Covent Garden, W.C., showed a considerable variety of *Nerines* in many brilliant and pretty shades of colour. Rosebud is a most charming variety with nearly erect, deep rose-coloured flowers with white base. It is also very distinct, which in these plants is a highly important item.

Messrs. Frank Cant and Co., Baiswick Rose Gardens, Colchester, staged a nice lot of Roses, of which Rayon d'Or, Irish Elegance, Mrs. Christie Miller (fine pink), Mrs. Alfred Tate, Snow Queen, Juliet, Mme. Jean Dupuy (in delightful form), Mrs. Foley Hobbs, Alexander Hill Gray (deep cream, and a fine autumn Rose), Lady Hillingdon (quite rich in colour), and Joseph Hill were a few among many good things. Lyon Rose was also very fine.

Messrs. Dobbie and Co., Edinburgh, displayed a capital assortment of early flowering Chrysanthemums. Goacher's Crimson, Golden Diana, Tuckwood Early Beauty (fine deep orange red), Radiana (reddish), Mrs. W. Sydenham (deep crimson), and Polly and Crimson Polly are a few among many that were good.

Mr. F. Bannister, Royston, Herts, showed a miscellaneous group of *Salvia* Pride of Zurich, with Verbenas and other things. Fans of Fern sporophylls six weeks after sowing were an interesting feature.

Messrs. B. R. Cant and Sons, Colchester, displayed a lovely lot of Roses, the flowers in the main fresh, clean and delightfully coloured. Of such were Lady Hillingdon, Lyon Rose, Mme. Edouard Herriot, Rayon d'Or, Snow Queen, Mrs. E. Powell (fine red), George Dickson (a glorious deep reddish crimson), Red Letter Day (fine semi-double crimson), Queen of the Musk (salmon and buff), Louise

Catherine Breslau (coppery tone) and Ellen Poulsen, all of which were charming in an excellent group.

Mr. Elisha J. Hicks, Twyford, had some excellent vases of Roses, of which Mrs. George Norwood (pink), one of the most beautiful and certainly one of the most fragrant, was charming. Mrs. John Foster is a new red raised by Mr. Hicks, a gloriously coloured Rose of pronounced fragrance with the Hugh Dickson habit of growth. It is as full of promise as it is of beauty and fragrance. Princess Mary (single crimson) and Joanna Bridge (creamy yellow) were also admirably shown. This excellent quartet was raised by Mr. Hicks.

Mr. G. W. Miller, Wisbech, arranged a table of Pyrethrums, Phloxes, Kniphofias, Michaelmas Daisies, Pentstemons and other showy plants. Rudbeckia Herbstone was very showy.

The Misses Hopkins, Shepperton-on-Thames, showed many seasonable hardy flowers, of which *Salvia uliginosa* and *Helianthus sparsifolius* were the more important.

Messrs. W. Cutbush and Sons, Highgate, N., showed a nice lot of Michaelmas Daisies, of which *Aster cordifolius* Ideal, a lovely mass of lilac blue, was one of the more charming. *Aster Amellus* in variety was also a feature.

Messrs. W. Wells and Co., Merstham, staged a lovely lot of Chrysanthemums, of which Golden Polly, Framfield Early White, Verona (bronze), Crimson Polly, Early Buttercup, Belle (mauve), and Le Cygne (pure white) were the more important.

Messrs. G. and A. Clark, Dover, showed Michaelmas Daisies in variety, *Helianthus sparsifolius* and other seasonable flowers.

Mr. G. Reuthe, Keston, Kent, staged excellent pots of *Colchicum speciosum* and *C. s. album*, together with *Zauschneria californica*, *Desmodium tiliaefolium*, *Tropaeolum tuberosum*, *Desfontainia spinosa*, *Tricuspidaria dependens*, *Cyclamen hederifolium album*, *Salix Bockii* (a most distinct species), *Gentiana Pneumonanthe* and other interesting plants.

Messrs. Allwood Brothers, Hayward's Heath, had a capital exhibit of Carnations, Mandarin, Champion (scarlet), Rosalind (fancy), Rosette, Mary Allwood and Salmon Enchantress being among the more important.

Mr. James Box, Hayward's Heath, showed an excellent group of hardy plants in season. *Aster Amellus* in variety, *Delphiniums*, *Anemone japonica* in variety, *Cimicifuga simplex* (in fine condition), *Aconitum Fisheri* (fine blue), *Pernettya mucronata alba* and *Helianthus sparsifolius* were excellent.

Messrs. George Bunyard and Co., Maidstone, showed such things as *Helianthus sparsifolius*, *Aster Peggy Ballard*, *A. White Climax*, *Heleniums*, *Tritomas* and other good autumn-flowering subjects.

Messrs. H. B. May and Sons, Edmonton, filled a table with an assortment of shrubby Veronicas, Ferns and Bouvardias. The Veronicas were very beautiful, such as Favourite (deep purple), Diamant (reddish), Valère (violet blue), Eveline (rosy pink), Coquette (mauve), Mauvena (deep mauve) and Gabrielle (rose pink) were the more distinct.

Roses from the Rev. J. H. Pemberton, Romford, were very charming. Callisto (cream and gold), Clytemnestra, Trier (blush white, gold anthers), Queen Alexandra (single white and pink), Danaë (cream and yellow) and Moonlight (white) were all beautiful in the cluster class. Rayon d'Or, Charles Le Lapisse (pink) and Mrs. Joseph H. Welch (rose pink) were other good things.

Mr. Ernest Ballard, Colwall, Hereford, had a superb table of new Michaelmas Daisies, King Albert (double blue), Edith Goodwin (violet blue), Corona (light mauve), Nancy Ballard (rosy), Rosy Morn (very pretty), Cloudy Blue (very beautiful), Ragtime (rosy mauve) and Lady Lloyd (deep rosy mauve) being some of the best in a fine lot.

Mr. J. B. Riding, Chingford, Essex, staged Dahlias admirably, the decorative sorts being much in evidence. Princess Juliana (white), Selma (pink), Mme. Capron, Harmony (lovely salmon pink), Mammoth (crimson), Sulphurea, Offenbach (golden), Geisha (very large, orange colour) and Delice (rose pink) being all distinct and good.

Messrs. H. J. Jones, Lewisham, filled a complete table with the best Michaelmas Daisies, of which Henry Adams (good blue), White Climax, Climax (very good), Magnet (mauve, very beautiful), Mrs. S. T. Wright (heliotrope), Ryecroft Pink, Colwall Pink, Avalanche (white), R. E. Hay (rose mauve) and Mrs. Heneage (good blue) were among the most important.

Mr. J. T. West, Brentwood, had an excellent group, of which Warneford (pure white) and Hornet (crimson Collarette) were very good.

Messrs. Stuart Low and Co., Enfield, showed some excellent Roses and Carnations. Lyon Rose, Juliet, Mme. Edouard Herriot and Ophelia were very fine. Constance (yellow) was particularly good.

Messrs. J. Cheal and Sons, Crawley, displayed a table of cut shrubs with Crabs and other things. They also arranged a good assortment of Dahlias, of which Loveliness (pink) and Mrs. F. Paton (crimson) were very fine. A large collection of Collarette and single varieties was staged.

Messrs. Carter Page and Co., London Wall, also staged a superb gathering of Dahlias, several sections of the flower being superbly represented.

Messrs. Piper, Barnes, had an exhibit of shrubs, Clematises and Vines in variety.

Messrs. W. Paul and Sons, Waltham Cross, were responsible for a great gathering of Roses. Juliet, Joseph Hill, Queen of Fragrance, Florence Haswell Veitch, Ophelia, Rayon d'Or, Waltham Scarlet and Marcella were particularly good.

Messrs. T. S. Ware, Limited, Feltham, contributed a representative gathering of Dahlias, Madonna, a fine pure white decorative sort, receiving an award of merit.

THE GARDEN.

No. 2290.—VOL. LXXIX.

OCTOBER 9, 1915.

NOTES OF THE WEEK.

The Loss of M. Pernet-Ducher's Two Sons.—English rosarians will learn with regret that the famous French rosarian, M. Pernet-Ducher of Lyons, has had the misfortune to lose both his sons in the great war. They were both killed on active service in the field.

Propagating Shrubs.—Many of the evergreen and deciduous shrubs can be propagated at this season, some of them in an open border if it is sheltered from the north and east. Laurels and Yuccas, among others, can be increased in this way. More tender shrubs like Buddleias and Garrya elliptica should be protected with glass. All can be rooted in separately, or if a shallow trench is taken out and sprinkled with sand, they can be rooted in much quicker.

An Autumn Bee Flower: Sedum spectabile.—This grand perennial is flowering here in profusion, and on bright days the large pink heads are nearly covered with bees. Readers on the lookout for a late bee plant should have this in their garden. As most gardeners are aware, this is by many termed a rock plant, and does very well in the rock garden, but I like to have large roots of it in the perennial border, close to the front, or have it in a prominent position in the "rock border." It can be planted at any time during the autumn or in March, and is propagated in the spring by division of the roots, each small root developing into a fine plant before the year is out.—E. T. ELLIS, *Westwood, Ecclesall, Sheffield.*

An Autumn-Flowering Primula.—*Primula capitata* is still looking very attractive in many gardens. Its flowers of rich purple, thickly coated with a white farina on the outer and lower parts, are borne in dense, globular heads from 6 inches to 9 inches above the mealy covered leaves. It cannot be considered a good perennial, and as it is readily raised from seed, it is best treated as a biennial, raising fresh plants every year, so as not to be without this fine late-flowering species. It requires a cool, shady position in good soil, and to be well watered in dry weather. A native of the Himalayas, it was introduced in 1850 from India by the late Sir Joseph Hooker. *Primula sphærocephala*, a Chinese species, introduced in 1908, is very similar to it, and may be nothing more than a Chinese form of *P. capitata*.

The Californian Poppy.—*Romneya Coulteri* has flowered unusually well, both in the middle of summer and again in the third week of September, when one might count as many as fifty blossoms on one big bush. The second burst of bloom came at the same time as that of some bushes of the common pink China Rose that are near them. The combined effect is singularly charming, and is still further enhanced by the silvery grey background provided by the Elm weather-boarding of the barn at the back, while the top of the picture is completed by a mass of closely clustered bloom of *Solanum jasminoides*.—G. JEKYLL.

SEDUM SPECTABILE, A USEFUL BEE FLOWER, IN THE PERENNIAL BORDER.

The New Laboratory at Wisley.—This building, which has been in course of erection for about twelve months, is making steady progress and nearing completion. When finished it will be fitted with electric light and well equipped with the necessary appliances for botanical and other scientific investigation. From an architectural point of view the building is very imposing and a worthy addition to the Royal Horticultural Society's Gardens. The society has been fortunate in procuring sufficient old tiles from Colchester to roof the whole building, while the walls are

built with large bricks from Holland. The Dutch bricks and weather-worn tiles give to the building an atmosphere of age that is quite in keeping with the beautiful gardens and surrounding Pine trees. Following the Surrey architecture, the tall chimneys are more or less circular, making the whole a large and imposing building. Early this year it was hoped that the laboratory would have been completed in time to be opened this month, but this has proved impracticable owing to the scarcity of labour.

The Double Pink-Flowered Bramble.—In bloom from July until September, the double pink-flowered Bramble, *Rubus ulmifolius flore pleno*, or *R. fruticosus flore roseo pleno* as it is known in nurseries, is a handsome plant for the shrubbery border and pleasure grounds; or if the old wood is removed each year after flowering in autumn, it is quite a good subject for arches, pillars and training to a wire or lattice screen. So thickly are the narrow pink petals arranged that they resemble a double Daisy, hence the name *bellidiflorus* by which it is sometimes known. It is increased by cuttings inserted in autumn in a cold frame, or on a border outside. A companion plant is the double white Bramble, *Rubus thyrsoides flore pleno*.

A New Chinese Leadwort.—In *Ceratostigma willmottianum* we have a very valuable autumn and early winter flowering plant for the outdoor garden. *Ceratostigma plumbaginoides*, or *Plumbago Larpentæ*, does not grow more than about 18 inches high, while the subject of this note in Miss Willmott's garden at Warley Place forms a spreading shrub some 5 feet high. Other distinguishing features are the brownish-red autumnal tint of the older plant, its more hairy foliage, and the flowers, which are a shade darker blue. The flowering season extending from August until November, a sheltered position is desirable. This may be on a south or west shrubbery border, and at the foot of a warm wall or fence. A well-drained sandy loam forms a suitable soil, to which should be added some flaky leaf-mould. It is increased by cuttings inserted in a heated propagating-frame in summer, also by division in spring, and layering.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

A Remarkable Lily.—I enclose a photograph of a fine *Lilium auratum*. This Lily was 9 feet 6 inches high, the stem was 7 inches in circumference about a foot above the base, and had seventy-six flowers and buds on it. The bulb has been planted about three years. These Lilies do well here, being planted on the top of a bank slightly below the edge of the lawn, where they get full sunshine, while the edge of the lawn shields the roots from the direct rays of the sun.—W. HUTCHINSON, *Whitegate, Bebington, Cheshire.*

Cotoneaster Simonsii as a Wall Plant.—In South Hants this *Cotoneaster* succeeds admirably as a wall plant and in almost any site, especially an eastern position, where it produces a full crop of richly coloured berries. On a northern site it grows equally well, but does not berry so freely. In Colwyn Bay, North Wales, I recently saw it covering quite densely a high wall, and by the aid of constant close clipping the plant was a dense mass of leafage, but there was no promise of berries.—SWANMORE.

Rose Diseases.—If, instead of notes on Rose mildew (page 445, September 11) Mr. Edward Mawley had detailed a method of combating black spot, I for one would have showered blessings upon him. This terrible disease has for the past two seasons played havoc in my garden, and its appearance is directly traceable to Juliet. From this variety it passed to *Beauté de Lyon* and others of the type, afterwards attacking numerous Hybrid Teas. Neither Seride nor Bordeaux mixture has had the least effect, and I am now contemplating lifting every bush, dipping them in strong fruit wash, and heavily liming the ground before replanting.—T. A. W.

Vegetable Marrows.—The interesting note by E. T. Ellis, page 469 of your issue dated September 25, on the proper storage of these for winter use is most opportune; but no mention is made of another important use to which these dried specimens may be put, which in these days of economy should be welcomed by all prudent housewives, namely, that cut up into slices they are most useful for mixing with Apples, where pies are in great request and these fruits scarce or costly to buy; while others, having to provide for large families, find, if a fair portion of a cut Marrow is added to the steak, it makes a little of the latter go a very long way.—F. R. CASTLE.

Apple Blenheim Orange.—On page 458, issue September 18, you allude to the reputation of Blenheim Orange as a shy cropper until the trees are twenty years old. At one time I was under this impression, but have quite changed my opinion since treating the trees in a different manner to the orthodox method of close pruning them when young. By allowing an extension of the main branches and summer pruning these as shoots are formed, with a view to the early maturation of growth, I have no trouble now to obtain fruit. On dwarf trees six years grafted I annually obtain heavy crops of highly coloured fruit.—E. M.

Wanted: A Remedy for Club in Cabbage.—Can any of your readers kindly tell me of a preventive of club in the Cabbage tribe? If so, I and many more will be ever grateful. I tried the well-known recipe of gas-lime without its having any beneficial effect. On my telling this to one who is recognised as a highly scientific authority

in the horticultural world, he advised me to use quicklime, so quicklime was used with a lavish hand, but still the club is as bad as ever. Strangely enough, on the ground which was the most limed, the club is worse than on that lightly treated, and I am thinking that lime and club hit it off well together. I have heard that salt is a preventive of club. It would be interesting to hear the result from anyone who has experimented with it. I should say this is a light, sandy soil, and the roots of my Cabbage plants were dipped in soot and lime water when planted. In view of the great need for every vegetable which can be grown at the present crisis, I was anxious to get a good supply for the next few months, and the result has been a great disappointment. Whoever can find a preventive or remedy for this scourge will do a national service.—B., *Weybridge.*

The Willow Gentian (*Gentiana asclepiadea*).—This beautiful plant is one of the never-failing

LILIAM AURATUM WITH SEVENTY-SIX FLOWERS IN A READER'S GARDEN.

joys of September. Now that I have it in fair quantity at the edges of the wide grass walks in the wood, it is delightful to notice the variety of the flowers, both in shape, colour and marking. What I take to be the typical form, from its being the most frequent, has a narrow funnel-shaped corolla, with the ends of the five sharply pointed lobes diverging, but scarcely recurved, and the colour is a deep violet-blue. But in many cases the lower part of the flower is so much swollen that the whole bloom has a true bell shape, and instead of the normal width of about three-eighths of an inch, it may measure as much as five-eighths at the swollen part and $1\frac{1}{2}$ inches across the mouth, and may have the sharply pointed tips of the lobes handsomely recurved. Some of the largest flowers are of a very beautiful pale blue colour, a grey-blue inside with the faintest tinge of green, while the outside has the same grey-blue, slightly suffused with the tenderest lilac. Looking into the throat of the flower, there is always, more or less visible, a marking of a double stripe of white, the two stripes converging to a point a little way

within the point of the lobe. In some cases the white marking is so broad and showy that it gives the flower a quite distinct character. The white marking in the plants that have pale blue colouring is of special refinement. The flowers commonly twelve to sixteen in number, stand up in pairs at every upper joint of the stem, where there are also a pair of Willow-like leaves, set laterally; the stems grow bending over, after the manner of Solomon's Seal, but in a lighter and more graceful way. The lobes of the corolla are normally five in number, but sometimes only four, while in the case of some of the larger flowers there are six. Probably these charming varieties have been observed at Wisley, where this handsome Gentian grows so freely.—G. JEKYLL. [Colour variations in these charming flowers have occurred at Wisley, also a beautiful white form, but the variation in the shape of the flowers has apparently not been observed. This Gentian loves shelter and shade; it succeeds in some localities and fails in others.—ED.]

AUTUMN.

AUTUMN laying here and there
A fiery finger on the leaves.

Calm is the morn without a sound
Calm as to suit a calmer grief;
And only thro' the faded leaf
The Chestnut pattering to the ground.

The seasons bring the flowers again
And bring the firstlings of the flock.

I can but trust that good shall fall,
At last—far off—at last, to all,
And every winter change to spring.

M. C. S.

Changing the Botanical Names of Plants.

Even though we may be as unwilling as is "H. P." (issue October 2, page 480) to accept new names for old favourites, a little reflection must surely convince us that an old name is not necessarily a correct name, and that the ends of science are not furthered by a "patriotism" which retains incorrect names merely because they have been given by "English botanists." I do not claim to be a botanist, but the attempt to discover the correct names of some garden plants soon showed me that, unless there is to be endless confusion, the naming of plants must follow certain rules, one of which is that the correct name of any plant is that which was first given to it. "H. P." with what appears to be insular prejudice, is presumably prepared to let the same plant have a different botanical name in every country in Europe. Again, if he had ever worked through a large genus, he would have realised that some of its first-discovered members were in the early days either wrongly grouped or not grouped at all, and his unwillingness to accept new names would seem to imply that, however great advances may have been made in our knowledge of any genus or group of genera, the members are not to be arranged in the groups to which they naturally and obviously belong, because it may then become necessary to change some old-established names. Even botanists do not change names merely for the sake of the change, and if "H. P." objects to the "awkward-sounding" generic name of *Matteuccia*, will he kindly suggest twenty euphonious titles that he would like to see conferred on the next new genera that botanists may be obliged to establish?—W. R. DYKES, *Charterhouse, Godalming.*

Storing Late Apples.—I was much interested in reading your reference to the storing of late Apples in "Notes of the Week," issue September 25. Expensively built fruit rooms are not necessary, though much appreciated where available. There are, in many establishments, sheds suitable for the storing of Apples, as they are fairly even as regards temperature throughout the winter and early spring months. Apples keep remarkably well in low sheds facing north, especially if a thick layer of straw or Fern is placed on the roof. Again, these fruits will retain their freshness if stored in heaps under a thick covering of tree leaves. I have had them in a very sound condition, so stored, as late as the following May. A naturally dry place is selected, having a north or north-west aspect; some dry, clean straw is laid down, on which the fruits are carefully heaped like Potatoes; more straw is put on, and then a layer of leaves about 2 feet deep; deeper if the leaves are plentiful.—G. G.

Solanum ciliatum.—Visitors to the Royal Horticultural Society's meetings will remember the fine imported fruiting branches of this plant shown last winter. I am aware that it is not a new thing, but it was new to me. Someone sent me a few seeds, and I am giving them a trial. I was told that it did not ripen its fruits outside in our climate, so I have kept the plants under glass, in pots, in a moderate temperature, and have given them painstaking cultivation and good fare. From the way the plant behaves here, I fear that we shall never get the decorative value out of it in this country that one had hoped. The Tomato-shaped berries, about the size of a Walnut and rich orange red in colour, are produced very scantily, sadly lacking in the freedom of fruiting which the sprays shown by Mr. Felton exhibited. The foliage is so prickly as to be almost pugnacious; there are sharp spines projecting at every point where one touches the plant, both on leaves and stem. My treatment and cultivation may be wrong, and it would be interesting to hear a report from anyone else who has tried it, but my present opinion is that *Solanum ciliatum* will be of little use grown here.—F. HERBERT CHAPMAN, *Rye*.

Buddleia Colvillei.—I lately saw this *Buddleia* flourishing in North Wales. In the gardens of Penrhyn Castle, on a wall facing south-east, a plant covers a space 15 feet high and fully 10 feet wide, where it annually flowers quite freely. In the gardens at Bodnant Hall, North Wales, I also saw it growing equally well, if not quite such a large plant. The natural semi-drooping habit of growth fits it well to grow as a wall plant, covering the space quite well. *Buddleia Colvillei* is a native of Sikkim, and one of the most striking members of this popular genus.—E. M.

Thalictrum dipterocarpum.—This will, I think, prove a decided acquisition to our Meadow Rue family. It delights in an open and sunny position, where it will then make a fine plant, throwing up an abundance of flowers on stems from 4 feet to 6 feet in height. The colour is purplish, with a tone of rose in it, so that, when planting it, the colour of its neighbours should be carefully considered, for a purplish rose tone does not blend nicely with some harsh ones. I think the most effective planting of it I have yet seen was in a well-chosen spot in front of some shrubs.—H. TURNER, *Serlby, Bawtry*.

Eucalyptus globulus and E. Gunnii.—I have had some considerable experience of *Eucalyptus globulus* and *E. Gunnii*, and quite agree with the editorial footnote, page 468, issue September 25, as to the hardness of the latter. A fine specimen of *E. globulus* grew in the gardens at Eaglehurst, near Southampton. It was fifteen years old, possessed a stem about 5 inches across, and had attained a height of 20 feet. Then came an

THE NOBLE PAMPAS GRASS WITH CEDAR OF LEBANON IN THE BACKGROUND.

exceptionally severe winter, the stem was frozen through, and, when thawed, split badly several feet up, and the tree soon died. I planted one in a garden in Bournemouth; it attained a height of 16 feet, and was then killed in the same way, though I took the precaution to wrap hay-bands round the stem to a height of 4 feet or so. *Eucalyptus Gunnii* was then planted, grew almost as rapidly as *E. globulus*, and soon made a fine specimen. It is very much hardier than the latter variety.—SOLENT.

FORTHCOMING EVENTS.

October 11.—Royal Botanic Society of London. Lecture by Professor W. B. Bottomley on "The Story of Soil Inoculation," 4 p.m. Fellows' Rooms Royal Botanic Gardens, Regent's Park, N.W.

October 12.—Royal Horticultural Society's Exhibition of Flowers, Fruits, &c., 1 p.m. to 5 p.m. Royal Horticultural Hall, Vincent Square, Westminster.

UTILISING THE FRUITS OF THE JAPANESE QUINCE.

THE Japanese Quince (*Pyrus japonica*) is this year producing exceptionally large crops of its aromatic fruits, and many readers have enquired if the crop can be used in any way.

We have referred the question to our esteemed correspondent "Anne Amateur," who replies that they may be preserved or made into jelly in the same way as Quinces by following this Kentish farmhouse recipe. Ingredients: Quinces, sugar and water. Method: Pare and quarter the fruits, boil in enough water to keep the pieces whole. When they are tender, take them out, and to each pound of Quinces add 1lb. of white sugar. Let them stand with the sugar on until the next day, when the syrup will be as light and clear as amber. Put them in the pan and let them boil twenty minutes; they never get hard.

For Quince jelly the water they were boiled in may be used to make a jelly of the parings. Add 1lb. of white sugar to each pint of juice and boil for half an hour.

Another pleasant way of utilising them is to convert them into jelly by the following simple process. Peel, core and slice the fruit into small pieces. Boil for two and a half hours in water sufficient to float the fruit. Strain the liquid through a jelly bag, and to every pint of liquid add a pound of sugar (good quality lump). Boil again until the whole is a thick jelly. Place in small pots, cover the jelly with a piece of white paper soaked in brandy as a means of preventing mould

growing on the jelly, and securely fasten down with air-tight paper.

THE SILVERY PAMPAS GRASS.

(*GYNERIUM ARGENTEUM*, SYN. *CORTADERIA ARGENTEA*.)

FROM the South American plains comes the noble Pampas Grass, which is hardy in most parts of England. The grand tufts of foliage and immense feathery blooms have long been well known and largely used in our gardens and outer grounds. The plant is dioecious—that is to say, the male and female flowers are borne on different plants. They vary a good deal from seed, some having much more fully furnished plumes; they also vary a good deal in colour, some being of the usual warm white, while others are tinted with rose colour or faint purple. It is better, therefore, in setting up a stock to see them in bloom in the nursery, so as to make sure of having a good strain.

AUTUMNAL ROSES IN SOUTHERN SCOTLAND.

By THE REV. DAVID R. WILLIAMSON.

SOME of the most effective of the late-flowering Roses on September 27 were Mrs. Wemyss Quin (bright apricot in colour), Majestic and Lady Clanwilliam, three of the finest of recent introductions; Lady Plymouth, almost pure white in its exquisite hue, and equally floriferous, a most reliable and picturesque variety for

and Irish Fireflame, the latter two varieties lustrous single—and singular—revelations of promise unrealised when they open, and therefore assuredly more impressive when in bud. Mr. George Taylor (of Dobbie and Co., Edinburgh) was not far off the truth when he wrote to me last January strongly recommending the culture of some of the China Roses of recent origination, these being in his estimation (and now also in mine) for purely decorative purposes among the loveliest of all.

Especially beautiful here on September 27 were such glorious creations as Comtesse du Cayla, Mme.

FLOWER BORDERS AT GOODNESTONE PARK, CANTERBURY.

AT Goodnestone Park, Canterbury, the residence of Mr. H. Fitzwalter Plumpetre, may be seen herbaceous borders illustrative of what may be done in a few months. It had been a vegetable garden for some two or three hundred years, a spacious, well-walled vegetable garden, and in a charming setting, for just beyond the wall on one side runs an avenue of fine Chestnuts; on the other the red-brown roofs of the Dower House show against distant trees; at the far end the square tower of the church rises grey against the sky; while towards the house a space of lawn and bright herbaceous beds leads now to this line of loveliness, where before it led only to Cabbages and utility. The old garden is cut across its length by a second wall, the mellow colour of which was delightful even against the greens of Cauliflowers and Beans, but it cried out for something more.

So the inspiration came. Openings were made through both the end and middle walls; these, being designed by a distinguished architect, were to be flanked by pillars made of the superfluous bricks. A wide pathway of turf cut from the park was laid from end to end, the church tower closing the perspective. On either side deep borders were dug (Asparagus, Cabbages and Beans having found another home in beds made where the old paths used to run), and then followed the pleasant task of planning the colour scheme. Entering, the eye

falls upon a wide corner of grey; the pale Santolina, the silvery Cineraria maritima, the greenish grey Phlomis, all showing soft as a cloud against a glowing background of Arctotis calendulacea—one solid mass of gold—and the brilliant Tagetes. Through the first archway, and there is, as it were, a patch of summer sky: Delphiniums, Salvia patens and tall Anchusas, making a wonderful blueness that throws into relief the delicate green spears of the Lyme-grass and the white of the Cosmos beyond.

And so it passes through white and palest yellow to the deep orange of Montbretias, Helenium grandicephalum striatum, the grand Helenium Autumnale and the blaze of Red-hot Pokers; while along the other side are great crimson Hollyhocks, massed pink Gladioli and Phloxes, Phloxes pink, Phloxes like old-fashioned chintz, Phloxes of every shade of mauve, down to the dark, almost purple, Le Mahdi. And there is the purplish pink of the graceful Desmodium and the dainty blues of Gilia capitata and the annual Lupines. Scabious in many soft uncertain tints, blue Lepotosiphon androsaceus, purple velvet Gladioli, lavender-coloured Nepeta, Lobelia syphilitica—these are but some of the glories that make these herbaceous borders a "joy for ever."

And all this glow of colour, this wealth of sweetness, has been produced between the months of

HERBACEOUS BORDERS IN THEIR FIRST YEAR AT GOODNESTONE PARK.

late autumnal bloom; Mrs. Edgar Burnett, generally regarded by rosarians as an improved representative or derivative of the fragrant La France, though here at least it does not produce such a number of flowers; Florence Forrester, an enormous white variety (quite unlike Snow Queen, unless in productiveness and the dimensions of its blooms), and with a quite perceptible fragrance; and Iona Herdman, which does not take very kindly to the somewhat exposed situation of my Rose borders here in the garden of Kirk House, and is of peculiarly dwarf and trailing habit, though its flowers are invariably exquisitely beautiful. I may venture to suggest to its distinguished raiser, who is to be congratulated on the creation of so many charmingly coloured decorative Roses, that a variety of greater vigorousness of habit than this veritable gem, Iona Herdman, would be a great acquisition.

But so long as we have such a splendid possession as Mrs. Wemyss Quin, which, in addition to its luminous aspect, is a fine grower and rich in central petals (which, alas! few modern decorative varieties are), we need not complain.

Other grand Roses that have been admirable here and elsewhere of late are the almost incomparable George Dickson (which has proved much more floriferous than I anticipated, especially in autumn, and whose only limitation is its pendulous tendency), Brilliant, Mme. Edouard Herriot

Eugène Resal, Mrs. Edward Clayton and Mlle. de la Vallette.

THE WILLOW-PLATE PATTERN TREE.

THE Willow-plate Pattern Tree is botanically known as *Kœlreuteria paniculata*. It is a native of Northern China, and was named after Joseph G. Kœlreuter, 1733-1806, once Professor of Natural History at Carlsruhe. It belongs to the same Natural Order as the Horse Chestnut, and it is a tree remarkable for its picturesque and irregular habit of growth. Its long, divided leaves are handsome throughout the summer and in autumnal hue, and the tree is beautiful when in flower. There are many examples of this tree in this country, one of the best known being that at the Chelsea Physic Gardens.

The flowering season is June and July. The flowers are yellow and disposed in large terminal panicles, which add to the quaint appearance of the tree. The flowers are followed by three-lobed inflated fruits that are very conspicuous in the autumn. The Willow-plate Pattern Tree is quite hardy in this country, and thrives in any ordinary garden soil, although in a sheltered position it flowers most freely.

February and August, very much to the credit of Mr. Woodruff, the head-gardener at Goodnestone Park, aided by the only two men left to help him—the rest of the garden staff having gone to fight. Nearly all the plants were either moved from other parts of the garden or grown from seed, so that, in this time of war, no money should be spent unnecessarily; indeed, as a symbol of the difficulties and drawbacks of this time, when labour and money alike must be given to the country as a whole, stands the unfinished second opening, its rough edges waiting for their pillars until more prosperous and peaceful days.

HARDY FLOWERS IN EARLY AUTUMN.

HERE, in a Surrey garden, the herbaceous border looks brighter at the close of summer than at any other time of the year. It is an easy matter to have a garden bright with the flowers of early autumn;

there are so many from which to choose. Shades of blue and mauve take the lead in the garden now. These colours are as plentiful in autumn as yellow flowers in spring, and the quiet beauty of blue and mauve flowers is in perfect harmony with the tints of autumn foliage. Michaelmas Daisies or perennial Asters are foremost among autumnal flowers. They look well in a border to themselves, backed by tall-growing varieties like *A. Novi-Belgii niveus*, a free-flowering white variety rising over 6 feet in height; *Amethyst*, with large open blue flowers, and its counterpart in flower, *Feltham Blue*, which grows a little taller and flowers a little earlier. *A. Lil Fardell* is one of the prettiest of the rose-coloured Michaelmas Daisies, and *Beauty of Colwall* is a handsome double variety with mauve-blue flowers. Among the lower-growing Michaelmas Daisies, *A. acris* and its variety *linifolium* make bold masses of colour. The Italian Starwort (*A. Amellus*), the dainty *A. ericoides* and *A. Thompsoni* are others worthy of special attention.

Late Phloxes and Michaelmas Daisies are admirable subjects to fill the gaps left by the early flowering Delphiniums. It is not an easy matter to keep up an unbroken succession of flowers in the herbaceous border, but it is one of the chief points to aim for. I know a garden where

two months ago there was a very large group of that exquisite *Delphinium Persimmon*. It is now an equally large bare patch—quite an eyesore to the border. If only Michaelmas Daisies had been planted around with late Phloxes, such as *nana cærulea*, and the pale lavender *Arendsii Hélène* in the foreground, what a difference it would have made to the present appearance of the border! The handsome Monkshoods are fine in early autumn, particularly *Aconitum Napellus* and *A. Fischeri*. The flowers are both beautiful and interesting, but the roots

are deadly poisonous. The blue Spider-wort, *Commelina cœlestis*, flowers at this season. It is an old-fashioned plant, but comparatively little known, having flowers like those of the *Tradescantia*. It delights in a warm border and a light soil, and it is advisable to protect its fleshy roots with a covering of ashes on the approach of frost.

Scabiosa caucasica flowers well into October; it is mindful of the wild Scabious of the cornfields that flowers much earlier. It is of perennial duration on light soils, but on heavy, damp soil it is apt to die out. However, it is readily increased from seeds in spring or by division in the autumn. *Stokesia cyanea*, with Scabious-like flowers, is an excellent companion plant to the former, flowering at the same time and answering to the same treatment. *Eryngium dichotomum*, a Sea Holly with small Thistle-like leaves and spiky blue heads of flowers, also *E. tripartitum*, look particularly handsome in the autumn. Neither must we omit *Sedum spectabile*, a favourite of bees and butterflies, or the Japanese Anemone with its numerous pink and white varieties. Japanese Anemones are among the most delightful

over-manuring of herbaceous borders is one of the commonest mistakes in the flower garden and a frequent cause of disease. The Silver Sage (*Perowskia atriplicifolia*), a half-shrubby plant with distinct silver grey foliage and blue and white flowers, is most effective in autumn, and it is worthy of extended cultivation.

Meadow Saffrons or *Colchicums* are included among the choicest flowers of September or October. They are often grown in borders with other hardy flowers, but they look far better when planted among grass, and we cannot do better than follow Nature's ways by growing them in moist grassy places. A very striking picture may be made by growing *Colchicums* over, or rather through a groundwork of Mossy Saxifrages. *Veronica subsessilis*, *Campanula rapunculoides*, *Catananche cærulea*, *Platycodon grandiflorum*, *Cichorium Intybus*, and, in shady places, the Willow Gentian (*Gentiana asclepiadea*) are a few blue-flowering subjects that will continue to bloom for many weeks to come.

Lobelia Tupa is a comparatively little known hardy plant now coming into flower. It hails from Chili, but in Southern gardens, at least, it

AUTUMN FLOWERS AT GOODNESTONE PARK, CANTERBURY

of all the early autumn flowers, and they look particularly effective when grown in bold groups by the water-side. (See illustration, page 497.) No garden, either large or small, should be without them. The variety of the Japanese Windflower known as *hupehensis* is uncommon and extremely beautiful; the flowers are of varying shades of pink. *Salvia nemorosa* is an old-world flower seen at its best in autumn, and the fine-leaved *Salvia uliginosa* is likewise good at this season. Plants of the Sage family, like *Salvias* and *Nepetas*, flower far better in poor soils than in rich. The

stands our winters well. It is, however, advisable to cover the roots with ashes or other loose material on the approach of frost. The flowers are of a bright brick red, and the plant grows to a height of about 5 feet. It is a really first-rate autumn flower, especially for a warm corner. It is also known as *Tupa Fuelli*. Dahlias for garden decoration should be selected with care. Many of the Cactus varieties that look so handsome when staged at flower shows are very disappointing in the garden. Owing to their weak stems the flowers are hidden under an uninteresting mass of

dense green leafage. The new decorative variety *Queen Mary*, a lovely pink, and the old white variety *Kaiserin Augusta Victoria* make quite a good display as border flowers. There is grace and elegance about the new and single *Cosmea*-flowered Dahlias, of which *Crawley Star* is perhaps the best known. There is certainly a future for this new departure, but the fanciful *Pæony*-flowered and *Collarette* Dahlias are of little or no use for garden purposes. There are many other plants that flower in autumn, such as *Achillea Ptarmica*, *The Pearl*, *Pentstemons*, *Cone-flowers* or *Rudbeckias*, *Verbena bonariensis*, with *Stachys*-like flowers borne well into October; *Hyacinthus candicans* (*Galtonia*), *Helenium autumnale magnificum*, and *Hunneemannia fumariæfolia*, a yellow *Poppy* suitable for a sheltered corner.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Ceanothus George Simon.—A beautiful form with pyramidal spikes of pale pink flowers.

shaped, after the *N. Bowdeni* type, and are coloured rich rose with white base. A plant of considerable ornament and merit.

These were exhibited by Messrs. Barr and Sons, Covent Garden, W.C.

NEW FRUIT.

Apple Edwin Beckett.—This fine culinary Apple, the cooking qualities of which were tested by the fruit and vegetable committee, originated among a batch of seedlings at Elstree. It is a handsome fruit of large size. Shown by Mr. E. Beckett, gardener to the Hon. Vicary Gibbs, Elstree, Herts.

The foregoing novelties were exhibited before the Royal Horticultural Society on September 28 last, when the awards were made.

NEW DAHLIAS.

Madonna (Decorative).—A gloriously pure white of magnificent proportions. From Messrs. T. S. Ware, Limited, Feltham, Middlesex.

Erin (Cactus).—The colour is deep orange in a remarkably fine flower. From Messrs. Burrell and Co., Cambridge.

These five were shown by Mr. J. T. West, Brentwood, Essex.

The foregoing Dahlias, having been adjudicated upon by a joint committee of the Royal Horticultural Society and the National Dahlia Society, carry the award of merit of the former and the first-class certificate of the latter.

EUCALYPTS FOR ENGLISH GARDENS.

By E. A. BOWLES, M.A., F.L.S.

THE pretty drawing and interesting note on *Eucalyptus Gunnii* in your issue of September 25, page 468, will, I hope, induce many to try some of the hardier Gums in sheltered nooks in their gardens. There are several species that are well worth a trial, and with anything like luck and a little care will certainly give a great deal of interest and pleasure for some years, even though they may not survive long enough to become giants like their forbears in their native wilds. There is an unfortunate and, I believe, undeserved prejudice against the family. One of our greatest gardeners has often told me he does not care for them and will not grow them, as he considers them dull and dingy compared with our native trees with their summer greens and autumn tints.

I wish he could have seen some groups and isolated specimens as I did a few days ago in a beautiful Sussex garden. One, *E. viminalis*, 20 feet high, rising out of a group of the hardy *Palm*, *Trachycarpus excelsus*, and backed by Oaks and Scots Pine, looked at a first glance like a column of blue wood smoke among the trees. Again, the species that does so well at Brightlingsea, and is nowadays generally considered to be *E. Gunnii*, had been planted to form a belt between two large groupings of such tropical-looking plants as *Drimys Winteri*, *Musa Basjoo*, *Phormium*, Palms and Bamboos, and the wonderful contrasts of colour and shape of these fine plants were greatly enhanced by the steely blue sheen of the Gums. Here in Middlesex I have been admiring to-day in my own garden the gleams of blue foliage of *E. cordata*, *pulverulenta* and *Gunnii* against the dark background of Yews and Ilex, and the Oaks and Limes of the park, now in their sombre early autumn tone of green.

I have struggled with many kinds here for about fifteen years, and although twice during that period a severe winter, or a sudden snap of cold following a mild spell, has robbed me of many of my best specimens, I have never been left totally bereft of Eucalypts. Even supposing the average life of a young tree is five years, it would be worth while planting them. They grow so quickly that in their second year they do much to show how blue they can look. *E. cordata* has ripened seed here before being overtaken by disaster, and thus left me the means of replacing it.

Seeds should be sown in April in the open ground, and the young plants moved into permanent quarters in the following spring. Greater hardiness is ensured if the plants have never been coddled, and, if never potted up, there is no fear of the main root becoming coiled as nearly always happens in a pot specimen, and is then one of the most frequent causes of trouble to the tree in after life.

THE NEW CULINARY APPLE EDWIN BECKETT.

Quite a useful addition. From Messrs. J. Cheal and Sons, Crawley.

Escallonia montevidense.—A very charming shrub with shining, entire leaves and terminal trusses of pure white flowers. Exhibited by Miss Willmott, V.M.H. Warley Place, Essex.

Aster King Albert.—A useful addition to the best of the midseason Michaelmas Daisies. The colour is lilac blue of a good tone. The flowers are nearly fully double and of large size. Height 2½ feet. Shown by Mr. Ernest Ballard, Colwall, Hereford.

Abutilon Triumph.—The largest-flowered form we have seen. The colour is rose of a pleasing shade. From Mr. Charles Turner, Slough.

Rose Hadley (Hybrid Tea).—This good addition to forcing and bedding Roses hails from America, where its forcing qualities have been fully tested. It is of rich crimson red tone and pleasingly fragrant. Shown by Messrs. Stuart Low and Co., Enfield.

Nerine Vivid.—The colour is rich scarlet, the form of the flower approximating to that of *N. cornucopia*.

Nerine Rosebud.—The most distinct thing seen for a long time. The flowers are trumpet

Carron (Collarette).—Guard florets brilliant scarlet, inner florets flaked scarlet and yellow. A striking novelty. From Messrs. Dobbie and Co., Edinburgh.

Sceptre (Cactus).—The colour is rosy purple in a well-built flower.

Bacchante (Decorative).—Rich crimson and white; very effective.

Garland (Collarette).—This is of rich scarlet tone, the inner florets soft yellow.

Ursa Major (Cactus).—A fancy variety, coloured yellow with red markings.

Searchlight (Cactus).—Handsome yellow self.

These were exhibited by Messrs. James Stredwick and Sons, St. Leonards-on-Sea.

Saucy (Collarette).—The whole flower is coloured sulphur yellow.

Landmark (Collarette).—Yellow with crimson markings.

Diamond (Decorative Single).—Intense Old Crimson Clove Carnation colour, with rich golden disc. Very handsome.

The Boy (Miniature Cactus).—This is of greenish white colour.

The Girl (Miniature Cactus).—The dominating colour tone is pink with a suffusion of red.

The Brightlingsea form of *E. Gunnii* appears to be as hardy as any, but is not quite so blue when it takes on mature foliage as in youth. *E. pulverulenta* is the bluest that is sufficiently hardy to stand our ordinary winters here. *E. cordata* comes next in blueness, and has more than once survived when *pulverulenta* has been killed. Our shallow soil and the underlying coarse gravel are not suitable for deep rooting, and I find most of my Gums blow over when they reach a height of anything over 10 feet, unless staked. Lately I have tried cutting out the heavy tops in late autumn, of those too tall for staking, and I believe if this can be done for a year or two until the main stem has become strong and thick, many of them will finally stand without support.

than any of these, except perhaps the beautiful *viminalis*, and certainly in its mature form, with drooping, sickle-shaped leaves of a dark greyish green, is rather dark in colour effect, and a curious contrast to the bright blue-grey of its juvenile form. *Cordata* and *pulverulenta* are the only two I know that retain the large, opposite and rounded leaves of their youth into middle age, and are as blue when 20 feet high as they were as yearlings.

Treseder of Truro used to send out a good form as *E. Beauchampiana*, but I have not seen it lately. One grew into a fine specimen here, about 15 feet high, and when the leaves took on the mature shape and hung vertically they still retained their blueness. Alas! it was blown over

JAPANESE WINDFLOWERS.

NOTHING can be said too favourable in the praise of these beautiful and elegant plants. As a supplement to the notes on page 471, issue September 25, may I make these remarks. The plants, varying somewhat according to variety, are rapidly increased by means of root cuttings, and do not always succeed when pieces are detached from clumps growing in borders. I find the white varieties difficult to grow well, no doubt on account of the soil being light and pervious. The largest of the whites is *Géant des Blanches*, which lived

AN AUTUMN SCENE AT KEW. JAPANESE WINDFLOWERS BY THE LAKESIDE.

It seems rather cruel to cut three or four feet off the top of a straight-grown tree, but it is better than allowing it to become loosened in the soil or blown over with every rough gale.

The portions cut off are wonderfully graceful in large vases in the house, and last fresh in water for several weeks, so this sort of adversity has its sweet usages. Seed of many varieties can generally be procured from the firm of MM. Vilmorin, Paris, and I can recommend the trial of any of the following species: Hardest.—*E. Gunnii*, *coccifera*, *Stuartiana*, *cordata* and *urnigera*. Bluest.—*E. pulverulenta*, *cordata*, *viminalis* and *coccifera*. Deep green with leathery leaves.—*E. obliqua*, *coriacea* and *robusta*. Pale green.—*E. resinifera*. The most generally known species, *E. globulus*, is far less hardy

in a gale and so much strained at the roots that it succumbed. *E. ficifolia* is the most gorgeous of all when in flower, but is so tender that it will not stand any frost, and has been badly damaged here in an unheated house. I saw a fine pot specimen last week standing out in a formal garden, and it had borne two large heads of its great scarlet flowers. So where protection in a warm house can be afforded it for the winter, this handsome species is well worth growing.

When next we get a three weeks' spell of skating, it is most likely that there will be many gaps among my Eucalypts here; but unless the cold or a descent through thin ice does for me also, I shall certainly begin again with all the kinds I can lay my hands on.

only a short time. Whirlwind, the most decorative of this colour, also died out after a time, and so did the old white, a particularly handsome border plant. The coloured forms, on the contrary, succeed very well, and a few of them are at present conspicuous in mixed borders for their general attractiveness.

Queen Charlotte in heavy ground is a noble plant, but for effect and profusion of flowers none is so valuable as *Profusion*. It is of similar habit to *Whirlwind*, but more abundantly flowered and is one of the plants in our borders for which people are constantly asking for a "little bit." A surface dressing of compost applied during the resting season is a valuable aid to the plants, which, as is well said, are best left without disturbance. R. P. B.

NOTES ON AURICULAS.

AT this period of the year the amount of work among the Auriculas is not great, but it is, nevertheless, important. If the weather is mild and dry, the treatment given last month may continue. With the approach of the winter the supply of water should be gradually decreased, and all dead leaves must be removed directly they will readily part from the stem. Where the plants have been grown in a wooden frame, it is now advisable to remove it from

that the Auricula dislikes anything in the way of coddling.

Starting a Collection.—A collection may be started at any time, and it is always best to begin with some of the named varieties, selecting those with a robust constitution and that are sure to give a good return in the way of bloom. Elaborate and costly structures are not needed; in fact, the more modest they are, the better are the results obtained. A cold frame with the sides and ends made of brick or wood will suit Auriculas

admirably, and there are few gardens of any size that do not possess at least one of these useful frames. The lights must be well glazed, or drip will be very troublesome just at a time when it is essential for the plants to be kept tolerably dry. For Auriculas a deep frame is not needed, and

each example should be fairly near to the glass. So the back rows of plants may be raised upon inverted flower-pots or on planks which rest upon bricks. The aspect of the frame should be north

during the greater part of the year, and for this reason Auriculas will thrive where other subjects will not grow.

A Selection of Varieties.—There are various sections, but to me the most beautiful are the alpines, and my dozen for a beginner would be as follows: Argus (a beautiful form which was figured in the coloured plate of *THE GARDEN* for July 4, 1914), Blue Bell, Duke of York, Evelyn Phillips, Firefly, Miss Ashton, Mrs. Martin Smith, Rosy Morn, Teviotdale, The Bride, Thetis and Uranie. The whole of the above could, no doubt, be purchased for 18s. The show or edged varieties are a little more costly, because they do not produce offsets so freely. An interesting dozen would include Buttercup, Mikado, Mrs. Phillips, Mrs. Potts, Ruby and Victoria, all selfs; Henry Wilson, Love Bird and Mrs. Henwood, green-edged; George Rudd, grey-edged; and Acme and Heather Bell, white-edged. In compiling the above list an eye has been kept on the cost, as it is useless to give an amateur a list of plants perhaps not yet in commerce or prohibitive in price.

T. W. BRISCOE.

STORING CANNAS AND DAHLIAS.

ALTHOUGH Dahlias are still flowering beautifully, it is well to look ahead and consider the question of storing the tubers. When properly stored the roots and tubers of Cannas and Dahlias are available in spring, when, without much

trouble, they can be increased and serve a very useful purpose in the flower garden again. Frost must be kept from the roots, and it will not do to pin one's faith too exclusively on straw. The latter material is certainly valuable for protection against frost, but, unless plenty of it is used, frosty winds will blow through it. This I know from experience. A fine collection of roots was stored in the centre of a floor of a loft; straw was placed on them, but it was not proof against the frosty wind blowing in under the door. These little details are sometimes overlooked. Quite dry sand is the best material in which to pack the roots. The crowns of each tuber must be covered, then there will be no danger of fungus attacking the upper parts of the tubers.

SHAMROCK.

CLEMATIS FLAMMULA IN THE FLOWER BORDER.

THIS good autumn climber is usually grown against a wall or fence, or in some rough, bushy place, but it has another very desirable use in the carefully arranged flower border. Just now (the last week of September), in a double border specially designed for this month's beauty, it comes over and among the earlier Michaelmas Daisies in great foaming waves, disappears for a moment behind a group of deep purple Daisies, and reappears beyond. At one point where it was desirable to break the general height of the border, there is a little tree of a silvery Willow, pollarded at about 6 feet high; it is cut back every year, and the summer growths are thinned and restrained. A Clematis Flammula is trained into it to run through and tumble out again among the Daisies below, where it first meets the fine tall Aster puniceus. Its general effect is then taken up by Aster paniculatus, with satisfactory pictorial effect. In another main flower border, where towards one end is a rather large group of Delphiniums, a Clematis Flammula is planted behind them. When the bloom of the Delphiniums is over, the stems are cut just below the seed-pods, and the growing Clematis is trained over the cut stems, which give just the right support. G. JERYLL.

TWO CHARMING LILIES.

BY SIR HERBERT MAXWELL, BART.

Lilium Henryi is one of the good things which we owe to Dr. Augustine Henry's exploration of Central China, where he discovered it at the close of the last century. It has proved to be thoroughly adapted to vigorous and permanent life in British gardens, where, indeed, it sometimes attains a stature which it has never been seen to reach in a wild state. The blossoms, which are freely borne when the plant is liberally treated, closely resemble those of the Japanese *L. speciosum*, except in their colour, which is a soft orange tending to apricot. The only fault of Henry's Lily is its sprawling habit, which should be met by planting it among shrubs that may give it support. It ranks among the Lilies easiest to cultivate. To obtain the best results, the bulbs should be planted 10 inches or 1 foot deep in rather strong loam with leaf-mould, adding some ground lime to correct acidity, and giving a good mulch of well-decayed manure and leaf-mould in early spring.

Parry's Lily (Lilium Parryi), on the other hand, must be classed as one of the most difficult subjects the British amateur has to deal with.

LILIUM HENRYI.

(Colour soft orange.)

the north side of any buildings to the south or west, where the extra light will benefit the plants and prepare them for the winter.

The Auricula as an Amateur's Plant.—Many plants, especially the Auricula, have been considerably improved by men who are generally spoken of as belonging to the working classes, especially the Lancashire weavers, and Ben Simonite of Sheffield, who was a working cutler. These facts should encourage others to follow in their footsteps, for there is no finality with such plants where careful cross-fertilisation is carried out and due regard is paid to selection. Auriculas as a whole do not require a vast amount of labour, but the amateur or fancier must take a keen interest in his plants; then the necessary attention becomes a pleasure. Where such interest and enthusiasm exist, the various requirements are soon discovered and carried out at the proper time. Without this love for his flowers little progress will be made, but it must be understood

Hitherto, I cannot lay claim to any success in growing it; but the superlative grace and commanding stature which distinguish this Lily when it is coaxed into displaying these qualities are an ample reward for any amount of pains and care. A native of Southern California, it is shy of our inclement winters, resenting hard frost equally with excessive wet. The finest examples I have seen are in Mr. A. Grove's garden near Henley-on-Thames, where, year after year, this Lily swings out a profusion of golden bells on slender, but erect, stems 8 feet high or more. It is not in every garden that Mr. Grove's prescription for cultivating it is easy to carry out, for it combines rapid drainage with a moist subsoil—conditions that may hardly be secured without subterranean irrigation. The bulbs should be nursed in pots for the first season after importation; then those that manifest healthy growth may be planted about 8 inches deep in a soil prepared of rather sandy loam, sharp grit or small gravel, leaf-mould and charcoal. If the garden is on chalk, that must be completely removed before the compost for the bulbs is laid down, and this must be done without check to perfect drainage. In cold districts some surface protection against frost must be provided.

FILBERT NUTS.

THERE are many plots in gardens which may be devoted to the cultivation of Nuts. Besides yielding nice crops in four years out of five, the plants form a good screen and shelter for other kinds of plants which would suffer from full exposure. A medium rich, well-drained loam is the most suitable; a soil in which water lies for a long time the most unsuitable. Nut bushes will grow freely on sloping ground, and on dry banks, too, if the loam is of a good holding nature.

Propagation is best carried out by layering and the insertion of cuttings through the autumn and winter months. Select low-growing shoots, cut away a small portion of the bark and wood from the under side, and then peg them firmly in the prepared soil, which should be of a gritty nature. Young, straight shoots should be selected for cuttings. They must be about eighteen inches long, and if stems free from suckers are required, all the buds must be picked out from the portion of stem buried in the ground. Insert the cuttings in a cool border 6 inches deep, and surround the base of each with coarse sand. Cut off the tips of each cutting, make the soil firm around the base, and tread it down well after each frost. All the pruning needed is the removal of cross-pieces and any central wood that would cause overcrowding. The necessary pruning should be done about the end of February, not in the autumn, so that there will be no danger of cutting away the Nut-bearing wood.

G. G.

THE CULTIVATION OF THE BLACKBERRY.

FROM time to time attention has been drawn to the great value of the Blackberry as an edible fruit. Efforts have been made to induce growers of fruit, particularly for preserves, to cultivate it extensively, but presumably because it is a British wild fruit, growing in quantity in the hedgerow and copse, its extensive cultivation is not thought worth while. At the present time, when so much is being talked and written about the cultivation of more ground, including the utilisation of waste land, the merits of the Blackberry should receive consideration. In giving a first-class certificate to Blackberry Himalayan Giant at a recent meeting of the Royal Horticultural Society, the members of the fruit committee, it is evident, realise the possibilities of this particular variety and the Blackberries in general. Sent to Wisley for trial in 1912 by Messrs. Laxton, Himalayan Giant was given an award of merit last year, which, after an extended trial, has been increased to a first-class certificate. Whether it has anything to do with the Himalayas, as the name suggests, is very doubtful. Some of the British Blackberries, if not identical, very closely resemble

Some years ago several American varieties were introduced, and these still find a place in fruit catalogues, familiar names being Wilson Junior, laciniatus, Lawton, Kittatiny, Parsley-leaved and Mammoth. Given favourable positions and attention, these have succeeded in some gardens; but remembering that such good fruits and quantities of them are produced wild, there appears to be ample scope for the hybridist, using the best of our wild species or subspecies, to produce sorts with large fruits of excellent flavour, which will grow and fruit freely in most positions—banks, hedges and on fences, sunny, but not well suited for other fruits. In the present necessity or desirability to make the fullest use of every possible home product, railway banks have been suggested as offering in many places excellent positions for the cultivation of the Blackberry. Several enquiries have been made during the last few years by one or two experimental stations respecting the best fruiting British Blackberries. In addition to *Rubus pubescens*, already mentioned, *R. dasyphyllus*, *R. villicaulis*, *R. thyrsiger*, *R. Selmeri*, *R. radula*, *R. pulcherrimus* and *R. nemoralis* produce good fruits in quantity, and appear worthy of attention from the hybridist.

An important point to remember is that in autumn, when the Blackberry is in season, all other small fruits are practically over. Already the Blackberry is well known for its rich and distinct flavour. Under cultivation, by hybridising and selection the improvement of this should be considered together with the size and quantity of the berries produced. As a preserve they are delicious, and there is little doubt that once the flavour became known with the masses, the demand for Blackberry jam and jelly would be enormous. Associated with Apples, both in jam and tarts, the value of the fruits is appreciated mostly in country districts. Bottled for

LILIUM PARRYI. PORTION OF A SPIKE.
(Life Size.)

it, however, yet the fact that in the "Handbook of the British Rubi," by the Rev. W. M. Rogers, one hundred and three species and numerous varieties are described suggests how difficult the British Rubi are to determine. Judged by the specimens growing at Kew, the Himalayan Giant Blackberry is very near to, if not identical with, the pillars labelled *R. pubescens*. This has the distinct, very thick stem and young growths 12 feet to 15 feet or more in length, with large panicles of big purple-black fruits.

use in winter, the Blackberry deserves attention and luscious ripe fruits served raw with cream can be strongly recommended.

The cultivation of the Blackberry presents no problems. Propagation is by layering, cuttings of firm young shoots in autumn, pieces of the thick fleshy roots, and offsets or suckers. The best method is to peg down the ends of the long young shoots in late summer; these soon root and may be severed and transplanted in spring. As with the Raspberry, the stems are biennial, and should be cut off at the ground level after fruiting and the young shoots tied in. Wires strained to strong uprights provide the best means of support for Blackberries when grown in quantity. They will thrive in most soils and positions, which must be sunny. The deep cultivation and manuring of the ground is necessary if the most is expected in the size and quantity of the fruits.

A. O.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Cucumbers.—Close attention to cultural details is absolutely essential to keep the plants in a good fruit-bearing condition during late autumn and winter. The temperature of the house must be kept as equable as possible. A minimum temperature of 70° will suit the plants till the cold weather sets in, when 5° lower will be better. The roots must be well supplied with moisture, but not excessively so. Syringe the foliage on fine days with rain water, and damp the paths and walls in the house two or three times a day. Should the "spot" disease attack the plants, syringing must be discontinued. Give the roots a little fresh material when they appear on the surface. Plenty of light is essential to healthy growth, therefore the glass must be kept quite clean both inside and out. Admit air on all favourable occasions.

Muscat Grapes.—The bunches should now be perfectly ripe, and in order to prevent the berries from shrivelling, the temperature must be maintained as equable as possible. A little heat must be kept in the pipes continuously, except on very bright days. The roots must not be kept too dry, and when water is necessary choose a fine day for affording it. A little clean straw placed over the border will prevent moisture from rising. Outside borders should be protected from heavy rains.

Plants Under Glass.

Primulas.—The late batch of plants should by this date be ready for their final potting. Five-inch pots are quite large enough for ordinary purposes, but if very large specimens are desired, 6-inch pots may be used. A position near to the glass in a light structure is necessary to promote a healthy growth, and a little artificial heat must be afforded when the nights are cold. The earliest plants will now be in need of a little stimulant.

Begonia Gloire de Lorraine.—A portion of the batch of this useful winter-flowering Begonia may now be allowed to flower. The flowers of the remainder must be removed, if they are not wanted till later. Attend to the tying of the shoots regularly, or the plants will grow out of shape. It is a great mistake to grow this Begonia in too high a temperature. This not only makes the plants grow weak and spindly, but the colour of the flowers suffers also. Admit air on all favourable occasions and keep the atmosphere drier than formerly.

The Flower Garden.

Dahlias.—As soon as the frost has destroyed the flowers, the plants may be lifted and placed in a shed to dry, previous to storing them away for the winter. See that each root is carefully and securely labelled. A dry shed is the best place in which to store them, but they must be made secure against severe frost.

Transplanting Trees and Shrubs.—Deciduous trees and shrubs may be transplanted now, providing the ground is in suitable condition. Lift them with as large a ball of roots as possible, and plant them without delay. To lift very large specimens successfully, the roots should be partially lifted the previous year to encourage the formation of fibres.

Violas.—These are most useful subjects for summer bedding, as they will flower profusely the whole of the season, providing they can be kept well supplied with moisture. If cuttings are not already inserted, no time must be lost in doing so. A shallow frame is all that is necessary to shelter them during the winter. Insert the cuttings thickly in a sandy compost.

Herbaceous Borders.—This is the most suitable time to overhaul borders of hardy flowers, as the characteristics and height of the various species can best be determined before they are cut down. If it has been decided to replant the whole of the border, an effort should be made to trench the ground, and plenty of well-decomposed farmyard manure should be dug into it. All the plants must be carefully labelled, and those which will require a little protection during very severe frost must be noted.

The Hardy Fruit Garden.

Wall Trees.—Materials must be got together for the replanting of all kinds of fruit trees on walls, so that there shall be no delay when conditions are favourable for this work to proceed. Fresh loam, wood-ashes and lime rubble are all that is necessary when the work of lifting and transplanting begins. As much of this important work should be done every season as time and labour will allow, and if it can be done before the turn of the year, so much the better.

The Kitchen Garden.

Seakale.—Some of the lower leaves may be removed to facilitate the ripening of the crowns. Towards the end of the month a few crowns may be lifted and placed in a shed for a week or two, preparatory to forcing them. If this vegetable is required in November, retarded crowns must be employed.

Asparagus.—When this is ripe enough, cut it down and clear the beds of weeds and rubbish. The beds should then be top-dressed with well-decomposed manure. It is also a good practice to sprinkle the beds with artificial manure for the autumn rains to wash down to the roots.

Potatoes.—Disease is likely to be prevalent among the main crop of Potatoes, especially on heavy land. Where time will allow, the tubers which were placed in their winter quarters should be overhauled, removing any which show the slightest sign of disease. Lime sprinkled among the tubers will be beneficial.

Runner Beans.—When frost is imminent, a portion of this crop may be protected with tiffany or some similar material. By this means the supply of this valuable vegetable may be prolonged till the end of the month.

Materials for Forcing.—Attention must now be given to the collection of materials for forcing early vegetables. Here we build large hot-beds of leaves and stable litter, on which are placed rough wooden frames, for growing all kinds of vegetables in the spring.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Fruit Under Glass.

Orchard-House.—Where there is permanent trees, every help should be given to thoroughly ripen the wood, now that all the fruit has been removed. The borders, however, must not suffer from want of water, especially in the case of stone fruit. Ventilation must be ample, and when the vacant spaces are used for housing plants, such as Chrysanthemums at this season, care should be taken that little or no water is spilt on the borders and pathways.

Early Vinery.—If the wood is sufficiently ripe and matured, the Vines must now be pruned if they are to be started during December, as six weeks should elapse between pruning and closing up the vinery for starting. After pruning, give the glass and woodwork a thorough cleaning down with plenty of strong soapy water, washing the glass laps well out with the full force of a hose. A safe and reliable dressing for the Vine rods is Gishurst Compound. Where bug is present, the crevices may be filled with this material after the rods have been washed with it in liquid form. This operation over, all the loose surface soil should be scraped off and the surface given a very slight loosening, not endangering any of the surface roots; then apply a top-dressing of good loam to which some reliable Vine manure has been added.

The Hardy Fruit Garden.

Apples, Plums and most other fruit trees can now be successfully transplanted. Where it is possible to do this work in the present month, a decided gain is obtained, a freer growth resulting earlier in the following season than if the planting was delayed till later in the winter.

The Kitchen Garden.

Broccoli.—In very wet and cold districts there is generally some trouble in wintering this vegetable. The most common cause of failure is growing it on ground too rich, causing a soft growth, which quickly succumbs to frost. The plants should now be lifted with as much soil adhering to the roots as possible; then, if a trench is taken out, the plants can be laid in with their heads facing north. It is very important that as much of the stem as possible is covered with soil, as it is generally at the neck where the plants are injured by frost.

Purple Sprouting Broccoli.—Unlike most of the other Broccolis, this is perfectly hardy; but if it is to succeed properly, any surrounding vegetables, such as Peas or Beans, must be cleared off to allow it full exposure to sun and air.

Cucumbers.—The plants which are expected to bear freely during winter should not be allowed to develop many fruits at present. Only a few should be allowed to form; then there are better prospects of more being produced as the plants are allowed to become established. Syringe freely in fine weather to discourage red spider, which seems to always abound where much pipe heat is present. A little stimulant may be applied to keep the plants a healthy colour.

Spinach.—Further thin out this by removing entire plants here and there where they are thickest. This can be done when Spinach is required for use in the kitchen. The remaining plants, by getting more exposure, will withstand the winter better.

Plants Under Glass.

Roses.—Most of the plants having finished their growth, encouragement should be given to thoroughly ripen the wood. Where a house is devoted to climbing Roses, any needless wood should be cut out to admit all the air and light possible. A drier atmosphere should now exist, unless there is any planting to be done, in which case syringing the foliage will help the plants to recover from the check of removal. This is also a suitable time to make an extension to an existing Rose border indoors.

Calanthes.—The flower-spikes on most varieties are now developing, while the foliage is maturing. Slightly drier conditions are necessary than was the case when the bulbs were forming, but this should not be overdone. Water must be applied with discretion until all the foliage is ripe.

Schizanthus which was sown during September must now be pricked off, putting three or four plants round the sides of 3½-inch pots. Keep them close for a few days until they have recovered from the check, then continue to grow coolly to induce a sturdy habit.

Euphorbias.—Both the *jacquiniæflora* and *pulcherrima* varieties should be given stimulants to assist in making a strong growth, which will ultimately develop large bracts. Being plants which succeed best in a restricted root run, they must be watered with every care if the lower leaves are to be retained.

The Flower Garden.

Dahlias should not be left out in too severe frost, as they are easily injured. The stems should be cut to within a foot of the tubers. Stand upside down in an open shed until they are dry enough for storing.

Herbaceous Border.—Many of the summer-flowering subjects are ripe enough to be cut over, but this should not be done prematurely, otherwise next season's growth will not be so fine. Many Asters will continue blooming for some weeks to come, should the weather remain open. Where Gladioli or annuals have been included in the border for effect, the bulbs and plants should be lifted as soon as they have done flowering, to help in maintaining a tidy and trim border.

Propagation.—All propagation by cuttings should now be brought to a finish if there has been a delay in securing cuttings. As many subjects can be started in heat during early spring, and then increased under better conditions, further increasing of stock should be deferred until then.

Castlemilk Gardens, Lockerbie, N.B.

COLOUR CHARTS.

A REPLY TO THE "REPLY FROM AMERICA."

IN her article in THE GARDEN of August 28, Miss Mary Youngs assumes an attitude of pugnacity that I am sure is not justified by anything I said in mine of last March and April. If she has so far misconstrued my remarks on those occasions as to interpret them as being intentionally antagonistic to any effort to standardise colours universally, I am sorry, but after carefully reading my article again, I cannot understand why she should have done so.

In the first place I referred to the substitution of Ridgway's Chart by the Royal Horticultural Society for the older "Répertoire des Couleurs" merely to prove that what was wanted was an authoritative pronouncement by a competent body of experts as to which was the best chart for general use. My contention was, and still is, that the mere fact that such a society, having sold to its members a certain number of the "Répertoire," and then adopting another for its descriptions, is likely to create the utmost confusion of ideas as to which is the better colour standard of the two. Even though it may logically be assumed from the sequence of events that Ridgway's Chart is considered the best, the adoption of one follows so closely on the sale of the other that it is more than likely to create in the public mind a feeling that it is useless to rely on any standard being finally adopted while one is renounced so lightly, after being introduced with such a fanfare of trumpets.

Miss Youngs' "common sense" advances as an argument in favour of Ridgway's Chart that it differs almost entirely in *nomenclature* from the "Répertoire des Couleurs." What on earth is the advantage of this? Giving a colour another name surely does not make it easier to create a standard. My "common sense" tells me that the more names it gets, the greater the confusion is likely to be as to what is really meant by any name. One would have thought that the simplest method would be to adopt existing names wherever possible, and so avoid the confusion that is likely to arise from the realisation that what was yesterday "eosine pink" has to-day become something else.

"There are fewer colours in Ridgway's Chart," says Miss Youngs. I have already pointed out that this is a doubtful advantage. "Inasmuch as in most cases a floral example has been given of each" in the "Répertoire," it would at least seem that the number is necessary, otherwise by what standard are these "examples" to be described? I am not by any means alone in my opinion that there are still many desirable tones missing, even where such a vast number are given.

I am pleased to learn that some infallible method of colour combination has been discovered that does not depend on the eye, although, as colour seems to me to be so essentially a matter for the eye, I am at a loss to understand how it can be so.

When it comes to the question of the "colour blind" or "colour dull," as Miss Youngs chooses to call them, my remarks were intended to point out that this condition of affairs is a great deal more prevalent than is generally supposed. She suggests that it can be ignored. But you cannot ignore it, because it is so prevalent, due possibly

to the fact that there is no colour education given to the general student in the same way that musical education is given. To-day most people are taught the difference between A, B and C in the musical scale; very few of us ever think of the difference between "eosine pink" and any other shade until the necessity arises for "matching," and then we find ourselves "colour dull."

If the "details of the bright or cloudy days, different soils, the difference in hue of the same variety of flower at different flowering seasons, &c.," are so "fussy," why do our artists prefer the "strong north light" and our photographers carefully test the actinic rays on every occasion before exposure, particularly on floral subjects? Surely it is due to the fact that they realise the immense difference the variations of light make on colour. Moreover, although the "few good garden colorists" could undoubtedly determine the standard colour of a flower, "matching up as accurately as possible in a clear light, not full sunlight," what happens to the poor bewildered user of the description when the effort is made to visualise the colour of the flower so described in "full sunlight" or any other?

I fully agree that a description like "eosine pink, mass effect a little paler," would be more likely to sell a plant than the sort of prescription of numbers and letters such as I described (with the intention of deprecating, not advocating its use); but what colour does "eosine pink" convey to the average mind, or the possessor of some chart other than Ridgway's?

I quite agree with Miss Youngs that the assertion of her American dealer, that "you cannot have a standard of nomenclature," is incorrect. You can have such a standard, but, like all other attempts at idealism, you have first to convince the remainder of the community that *your* standard is the right one, or at least the best obtainable. Now, let us assume that it has been indisputably proved that Ridgway's is the best; what is the next step? To bring the published descriptions of flowers into line with it. I pointed out last March some of the difficulties of this, and to none of these difficulties does Miss Youngs offer any solution.

One remark in the article throws a lurid light on the happy position of the dealers in America, as compared with those on this side. I am sure the fact that "the dealers could easily afford eight dollars" as compared with the private purchaser's four dollars each is something not dreamt of in the dealer's philosophy here, where some importance is attached to the words "trade terms." With reference to the firm who "advertise in their catalogues that they have in their office a copy of the Royal Horticultural Society's Chart, which is the Royal Horticultural Society's Chart?" and if it is the "Répertoire des Couleurs," of what use is it to Miss Youngs, who apparently swears by another? Moreover, diligent search has failed to convince me that the catalogue descriptions of that firm are any more reliable than others. I know several other firms who have a copy of the same chart, and it is not always in the office, but is sometimes in the nursery assisting in the comparison and revision of descriptions.

Of course, in pointing out the discrepancies between various descriptions as given in catalogues I was endorsing a plea for a standard of colour nomenclature. But why "confessions," Miss Youngs? I know of no reason for confessing. I made a plain statement of things as they are, hoping some effort would be made to overcome them. We adopted the "Répertoire" without

realising how difficult it would be to make it of any real use. The question is now: Will it be wise to scatter broadcast another, without any attempt to meet the difficulties I have summarised, and with no reasonable assurance that Ridgway's Chart spells finality? What the "dealers" require is some surety that any reform they may undertake will be worth the effort. What those of us who spend our time in designing gardens and the planting arrangements for them desire is a dictionary of flowering plants with a consistent and reliable description of colour, according to any known standard.

Colchester.

GEORGE DILLISTONE.

ANSWERS
TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

VIOLET LEAVES (H. W. T.).—The violet coloration on the under side of the Violet leaves is nothing to fear; the colour is characteristic of certain varieties under some conditions of growth. There is a little red spider present, which should be kept down by spraying now and then with water.

PÆONIES FROM SEED (Four Oaks).—Cut the capsules or seed-pods when signs of bursting are first noticed, and lay them out in a dry place on a sheet of paper. At the end of a month, when all the seeds will be free, sow them in a shallow drill of prepared soil in the open, covering them about half an inch deep. If you possess a greenhouse, the seeds might be sown in pans, and remain in them till ready for transplanting to a nursery bed next August or September. If of good quality, the seeds will probably vegetate during the spring of 1916.

INCREASING GYPSOPHILA PANICULATA (W. S.).—If you refer to the typical kind, raising it from seeds sown between now and the end of the year would yield the greatest return, as for a few pence a hundred or two may be raised. The plant, owing to the often contracted neck of the rootstock, is difficult—sometimes impossible—of increase by division in the ordinary way, but is increased by means of heel cuttings secured in spring and inserted in sandy soil in a cold frame, and by root cuttings inserted from November to January inclusive. The latter consist of inch-long pieces, and should be inserted in pots or pans and given greenhouse treatment. It is work, however, better suited to the commercial gardener, and, generally speaking, seedling raising will, for you, be found the better way. In the young state the plant is a slow grower.

TULIPS AND ANEMONES (F. P.).—Without knowledge of the quality of the bulbs of the Tulips and the time they were planted, both of which would have an important bearing on the point, we should pronounce against the fairly stiff soil as a predisposing cause. Then, in not a few districts, exceptional and prolonged drought was experienced last spring—in our own case the beds of Darwin Tulips had to be repeatedly soaked with water; and, further, disease was rife in certain varieties, some of which, despite large size and apparent soundness when planted, never grew at all. In the case of partly diseased bulbs, few, if any, root fibres would be formed, and in such case the bulbs, drawing no support from the soil, would exhaust themselves by their flowering. Generally, therefore, we incline to the view that the bulbs were not absolutely free from disease when planted, and, producing fewer root fibres than usual, their diminished size followed as a matter of course. Our sympathies are with you, inasmuch as we had to discard some hundreds this year for similar reasons, bulbs, too, that at planting-time looked sound enough. In respect to soil, you might with advantage add much sand to it to modify the stiffness, and plant as early as possible. Where manure is employed, let it be well decayed, and dig it in some inches below the bulbs.

TREES AND SHRUBS.

BAYS NOT DOING WELL (A. H. Rydon).—Your Bays are evidently suffering from a combination of the troubles you mention. Wind, drought and lack of food material all play their part in the ill-health of the plants. They should be watered regularly and fed with manure water, bone-meal, or some other fertiliser at frequent intervals, at least once a week during the growing period and every two or three weeks during the time when they are at rest. The most likely method of improving the condition of the trees is to cut them well back in March or early April, and stand them in a light and warm glass structure where they can be syringed several times a day and the surroundings kept moist. This, with judicious feeding, ought to effect an improvement. Boxes and Yews may both be used in the way you describe, while for a position sheltered from wind the Myrtle will make a good tub plant.

COVERING WALL OF BUILDING (Ellwood Holmes).—If it is desired merely to hide the stonework from view with plants of close clinging habit, or such, at least, as would require no nailing, you had better resort to such things as Ivy in variety, *Vitis inconstans* and *Euonymus radicans variegata*, all of which are close growing and self supporting. There are, of course, numerous flowering climbers, but these would require nailing and training from time to time. If, as we understand it, a simple screen for the wall only is required, we should suggest the *Vitis* for the south side, and Ivy in one or two sorts for the northern exposure. By planting a number of young plants well, a screen would be formed from the base of the building. If we have not met your requirements, please do not hesitate to write us again on the matter, with, if possible, fuller particulars.

TRAILING SHRUBS FOR WALL (E. A. C.).—We fear the near proximity of the Laurel hedge, the dryness of the position, and the narrowness of the border are opposed to much success in the shrub line, the more serviceable of which you appear already to have in use on the opposite side of the drive. Cannot you repeat, with certain modifications, what already exists on the other side? Anything opposed to it would be incongruous. Three good plants would be *Cotoneaster microphylla*, *Iberis sempervirens garxiana* (a fine trailing Candytuft), and *Clematis montana*. These are the most likely to be in agreement with what already exists, though, of course, you might plant other sorts of Rock Roses. The plants would be assisted to greater progress if a trench were dug out the whole length of the hedge and the root fibres of the Laurels cut close back.

ROSE GARDEN.

ROSE SHOOTS FOR INSPECTION (H. E. R.).—There is no disease evident on the Rose shoots sent. They are dead, but the cause of death must have operated in the lower part of the bush.

FRUIT GARDEN.

APPLE TREE DISEASED (C. L. A.).—The Apple tree is attacked by the woolly aphid. A forcible spraying with paraffin emulsion, or painting the affected parts with methylated spirit, would be the best thing to do, and it should be done at once, as there are few worse pests of Apples than this.

PEARS NOT JUICY OR SWEET (Subscriber).—There must be something radically wrong with their culture; perhaps they were gathered too soon. If it is so, this would account for it, or perhaps they are growing in soil which is too poor and dry. If the trees are not too old, lift and replant in a border of good turfy loam, mulching the surface soil over their roots in summer with well-decomposed manure, 4 inches deep. This will prevent the evaporation of moisture and encourage the growth of surface roots and nourish them. Water the trees through the manure freely in dry weather.

SEASON IN WHICH VARIOUS APPLES ARE RIPE (E. M. H.).—Court of Wick, valuable dessert Apple, in use from November to February; Yorkshire Greening, cooking Apple, in use from November to January; Bess Pool, a valuable Apple for cooking or dessert, in use from Christmas to March; Northern Greening, cooking Apple, in use from Christmas to April; Cockle (or Nutmeg) Pippin, dessert Apple, in use from January to April; Miller's Seedling, not known, probably a local name. If you send us a fruit we may be able to identify it. The Pear is Broom Park, an excellent dessert variety, ripe in January.

MISCELLANEOUS.

WANTED: A SUBSTITUTE FOR KAINIT (Miss Holmes).—There is no substitute for kainit, except burnt wood and plant ashes; but most heavy soils contain a large proportion of potash, which can be rendered available by dressings of fresh air-slaked quicklime.

NAME OF PLANT.—Mrs. A. H.—*Senecio tanguticus*.

NAMES OF FRUIT.—Lady Franklin.—1, Cellini; 2, Mank's Codlin; 3, Malster; 4, Bismarck; 5, Stamford Pippin; 6, Hawthornden; 7, Doyenné du Comice; 8, Beurré Diel.—H. S.—1, Clapp's Favourite; 2, Doyenné Boussoch; 3, Tower of Glamis; 4, Worcester Pearmain.—F. N., Glos.—1, Princess; 2, Ecklinville; 3, Coe's Golden Drop.—E. H. C. T.—1, Marie Louise d'Uccle; 2, Marie Louise; 3, Louise Bonne of Jersey; 4, Winter Nelis.—A. M. C., Devon.—Flat Apple, The Queen; conical Apple, Lane's Prince Albert.—F. E. W.—1, Newton Wonder; 2, Lord Suffolk; 3, Cellini; 4, Stamford Pippin; 5, Brandy Apple.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY'S EXHIBITION OF BRITISH-GROWN FRUIT.

THE annual exhibition of British-grown fruits was held on October 5 and 6, and from many points of view must be regarded a distinct success. In certain directions, more particularly the nurserymen's open division, it is doubtful whether finer produce has ever been staged, the leading class, in which a table space 30 feet by 6 feet was allowed, bringing out five superb collections. These, indeed, were one of the chief attractions of the show. Hardly less meritorious were many of the fruits in the succeeding classes, and generally throughout the show high excellence prevailed. The pot-grown fruit from Hereford was very fine, brilliant colouring being quite a feature of the many Apples shown. Apples Charles Ross and Rev. W. Wilks, from Langley, astonished everybody by their size and good colour. Ripe dessert fruit in collections, and Grapes also, we have seen more finely staged generally, and in both of these a falling off in quality was noticeable. The greater falling off, however, was in the single dish classes, which hitherto have been a strong feature. All the same, the wealth and excellence of the exhibits reflected the highest credit on the cultivators concerned.

DIVISION I.

Fruit Grown Under Glass or Otherwise.

For a collection of nine dishes of ripe dessert fruit three exhibitors staged, the first prize going to the Duke of Newcastle, Clumber, Worksop (gardener, Mr. S. Barker), for an excellent lot. There were Grapes Muscat of Alexandria and Madresfield Court, Dymond Peach, Humboldt Nectarine, Hero of Lockinge Melon, Marguerite Marillat and Doyenné du Comice Pears (the former of superb colour and size), with Wealthy and Cox's Orange Pippin Apples. Second, Lord Somers, Eastnor Castle, Ledbury, whose Black Alicante Grapes were excellent. Apple Charles Ross was a particularly fine dish, and Pitmaston Duchess Pears handsome and well coloured.

For a collection of six dishes of ripe dessert fruits, C. A. Cain, Esq., Welwyn (gardener, Mr. T. Pakeman), was first, his best dishes being Peaches Sea Eagle and Lady Palmerston, both of which were superb. Pear Doyenné Boussoch, Melon Ringleader, and Madresfield Court and Muscat of Alexandria Grapes were also included. Second, Major St. Maur, Newton Abbot.

For six distinct varieties of Grapes, two bunches of each, only two competitors staged, the first prize going to the Duke of Newcastle, Clumber, Worksop (gardener, Mr. S. Barker), for an admirable lot. His centre was a giant bunch of Gros Guillaume, the finest in the whole show. Others of great merit were Gros Colman, Muscat of Alexandria, Mrs. Pearson, Alicante and Madresfield Court. Lord Hillingdon, Sevenoaks, Kent (gardener, Mr. J. Shelton), was second, Black Alicante and Muscat of Alexandria being his finer bunches.

For four varieties of Grapes, two bunches of each, only one exhibited, C. A. Cain, Esq., Welwyn, being awarded first prize for fruits not of the highest quality. The best examples were Muscat of Alexandria and Madresfield Court, both of which were well coloured.

For two bunches of Black Hamburg Grapes, Lord Hillingdon, Sevenoaks, Kent (gardener, Mr. J. Shelton), was first with well-coloured fruits. Second, Basil E. Richardson, Esq., Ware, whose bunches were larger, but lacking the finer finish of the first-prize lot.

Two bunches of Grape Mrs. Pince: First, The Duke of Newcastle, Clumber, Worksop (gardener, Mr. S. Barker), who set up a couple of admirable bunches. Second, G. Miller, Esq., Radlett, with large bunches that would have been improved by more liberal thinning.

Two bunches of Grape Alicante: Eight competitors staged, the first prize going to Mrs. W. Raphael, Castle Hill, Englefield Green (gardener, Mr. H. Brown), with excellent, well-finished bunches. Lord Somers, Eastnor Castle (gardener, Mr. G. Mullins), was a close second, having larger bunches of somewhat smaller, less well-finished fruits.

Two bunches of Grape Madresfield Court: The Marquis of Salisbury, Hatfield House, Hatfield (gardener, Mr. H. Prime), was first with nice bunches of this excellent sort.

Two bunches of Grape Prince of Wales: Sir Walpole Greenwell, Bart., Marden Park, Woldingham (gardener, Mr. W. Lintott), was first of three exhibitors, his bunches being a very fair sample. Second, G. Mayer, Esq., Woldingham.

For two bunches of any other black Grape, the first prize was awarded to Muscat Hamburg, but no card indicated ownership. Second, Viscount Enfield, Wrotham Park, Barnet (gardener, Mr. H. Markham), whose fine bunches of Appley Towers, well berried and highly finished, merited, we thought, first prize. There were seven competitors in this class.

For two bunches of Muscat of Alexandria Grapes the first prize was awarded the Duke of Newcastle, Clumber, Worksop (gardener, Mr. S. Barker), who staged a pair of superbly coloured bunches. Second, C. A. Cain, Esq., Welwyn (gardener, Mr. T. Pakeman), who also had excellent examples, less finely coloured than in the first-named set. Seven exhibitors staged.

For two bunches of any other white Grape the first prize went to C. A. Cain, Esq., Welwyn, for Lady Hutt: Mr. S. Miller, Radlett, staging the same variety and taking second prize.

For a collection of hardy fruits, space not exceeding 12 feet by 3 feet, F. Bibby, Esq., Hardwick, Shrewsbury (gardener, Mr. J. Taylor) was first with an admirable

collection, in which Peaches, Plums and Nectarines were strong features. Peaches Late Devonian, Gladstone, Late Admirable and Alexandra Noblesse were very fine, as were also Nectarines Peach and Prince of Wales. Plums President, Monarch and Coe's Golden Drop, and Apples Peasgood's Nonsuch, James Grieve, Wealthy and Charles Ross were also of high merit. Second, Lord Somers, Eastnor Castle (gardener, Mr. G. Mullins), whose dishes of Apples ranked high. Royal Jubilee, Charles Ross, Emperor Alexander, Blenheim Orange and Gascoigne's Scarlet were very fine. Plums, Peaches, Nectarines and Morello Cherries were very fine in the front row. Third, Major Powell Cotton, Birchington (gardener, Mr. J. Cornford), who staged Figs, Plums and Peaches excellently.

For a collection of orchard-house grown fruit and trees in pots, space allowed 24 feet by 6 feet, only one competitor, The King's Acre Nurseries, Hereford, staged, the pot trees being the admiration of all. Of these, Apples Blenheim Orange, Newton Wonder, Emperor Alexander, Gascoigne's Scarlet, Cox's Pomona and King of Tompkins' County were all superb in colour and fruit. A tree of Peach Golden Eagle was well fruited, while, along the front, dishes of Apples, Pears, Plums and Peaches were freely displayed.

AFFILIATED SOCIETIES' CHALLENGE CUP.

The Colchester and District Gardeners' Association were the winners of this challenge cup, awarded for Apples and Pears. Of the Pears, Souvenir du Congrès, Doyenné du Comice and Beurré Diel were splendid; likewise the dessert Apples Cox's Orange Pippin, Ribston Pippin and James Grieve. The Ipswich and District Gardeners' Association contested this class well, and could only have been a very few points behind the winners.

DIVISION II.

Open to Nurserymen Only.

For Fruit Grown Entirely Out of Doors.

This class (space allowed 30 feet by 6 feet) was the great attraction of the show, five competitors putting up magnificent collections, no fewer than three gold medals being awarded. Messrs. H. Cannell and Sons, Eynsford, Kent, won one of these coveted honours with a grand lot of fruits, in which Apples, Pears and Plums of the highest quality were staged. Plums Belle de Septembre and Coe's Golden Drop and Apples Wellington (regarded by the judges as the finest lot ever staged), Emperor Alexander, Bramley's Seedling, Rev. W. Wilks, Coronation, Lady Sudeley (brilliant colour), Gascoigne's Scarlet, Mrs. Barron, a monster dish of Peasgood's Nonsuch, Bismarck, Potts' Seedling and Blenheim Orange were superb. Pears King Edward, Durondeau, Conference and Marguerite Marillat were grand. Nearly 200 dishes were staged, and the arrangement was admirable. Messrs. George Bunyard and Co., Maidstone, also won a gold medal for a superb lot of Apples. The Houbion (handsome colour), Charles Ross, Gascoigne's Scarlet, Allington Pippin, Norfolk Beauty, Lady Sudeley, Wealthy, Coronation, James Grieve, The Queen, Grenadier (yellow skin), and Ecklinville being the best. Of Pears, Beurré d'Avalon, Louise Bonne of Jersey, Durondeau, Conference, Doyenné Boussoch, Fondante Thirriott (very handsome) and St. Luke were all fine. Damsons and Plums were also noted. A most artistic arrangement. Mr. J. C. Allgrove, Middle Green, Langley, Slough also secured a gold medal for a grand collection, his tray of forty fruits of Rev. W. Wilks eliciting the admiration of all, some of the largest fruits weighing 26oz. Charles Ross and Peasgood's Nonsuch were set up in like fashion, their colour and form being a great attraction. Cox's Orange Pippin, Lane's Prince Albert, St. Edmund Pippin, Wealthy, Worcester Pearmain, Warner's King, King of the Pippins, Lord Derby, Blenheim Orange and James Grieve were the more imposing dishes. Of Pears, Beurré d'Anjou, Bellissime d'Hiver, Durondeau, Pitmaston Duchess, Conference, Louise Bonne of Jersey, Autumn Nelis and Duchesse d'Angoulême were the finer examples. Bullace The Langley was notable among other fruits. The arrangement was in every way excellent, the fruits of the highest quality.

Messrs. J. Cheal and Sons, the well-known firm of Lowfield Nurseries, Crawley, were awarded a silver-gilt Knightian medal for a capital display in this class. Very handsome were the large baskets of Lord Derby, Warner's King, Lane's Prince Albert and Crawley Beauty.

A silver Knightian medal was awarded to Messrs. W. Seabrook and Sons, Chelmsford. Their baskets of well-coloured Charles Ross, Cellini, The Queen, Worcester Pearmain and Duchess' Favourite were much admired.

For a collection of fruit, 20 feet by 6 feet, Mr. R. C. Notcutt, Woodbridge, led the way with a superb lot of fruits, gaining a silver-gilt Knightian medal. His best Pears were St. Luke, Beurré Alexandre Lucas' Conference, Winter Orange and Pitmaston Duchess. Of Apples The Queen, James Grieve, Potts' Seedling, Rev. W. Wilks, Peasgood's Nonsuch and Rivers' Codlin were all fine.

The Barnham Nurseries, Limited, Barnham, Sussex, showed Apples of wonderful colour, which gained for them a silver-gilt Banksian medal. Newton Wonder, Gascoigne's Scarlet, Barnack Beauty and Adam's Pearmain were specially good.

Messrs. S. Spooner and Sons, Hounslow, were awarded a silver Knightian medal for a collection of Apples comprising Lane's Prince Albert, Bismarck, Encore, Lord Derby and The Sandringham, all first-rate cooking varieties.

Mr. Charles Turner, Slough, gained a silver-gilt Banksian medal for a nice lot of fruits, of which Apples were a strong feature. Arthur Turner, Charles Ross, Warner's King, Peasgood's Nonsuch, Potts' Seedling and Royal Jubilee were the best. Of Pears, Louise Bonne of Jersey and Beurré Hardy were very handsome.

THE GARDEN.

No. 2291.—Vol. LXXIX.

OCTOBER 16, 1915.

NOTES OF THE WEEK.

Our Special Rose Number.—Few flowers, if any, give so much real enjoyment over a long period as the modern Rose, and there can be no refuge so peaceful and refreshing like unto a garden of Roses. Following our usual custom at the commencement of the Rose planting season, we shall devote a considerable portion of our next issue to special articles on Roses. Mr. Edward Mawley, V.M.H., president of the National Rose Society, has contributed a most instructive article on "Roses for Walls." Miss Ellen Willmott, V.M.H., has kindly promised to write upon "Roses in the Wild Garden." Profusely illustrated articles on "Standard and Pillar Roses," "New Species from China," "Roses for Clothing Old Trees," and "The Rose Garden of Europe" will appear, by some of the best authorities on our national flower. In addition, a coloured plate of a new single Rose will be included. The price will be one penny, as usual.

Apple Dumelow's Seedling or Wellington.—This late-keeping Apple, in season from November till March, is a great favourite in the kitchen, as the flesh becomes nearly transparent and it has a refreshing, acid flavour when cooked. Its market repute is very high, and it is claimed to be the best of all Apples for cooking. It is best grown as a bush on the Paradise stock. However, on cold soils it is not a success, as it is subject to canker, while Newton Wonder and Bramley's Seedling are preferable for orchard culture. It is extensively grown in Kent, and the basket of fruits of this variety in the gold medal collection shown by Messrs. H. Cannell and Sons, Eynsford, Kent, at the recent exhibition of British-grown fruit was regarded by the judges as the finest lot ever staged.

Choice Shrubs Fruiting.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. E. A. Bowles showed fruits of *Davidia involucrata* from Mr. Christie's garden at Framlingham Pigot, Norfolk. The fruits were collected from a plant growing in the open air, but it is not certain that the seeds were properly formed. At the same meeting Mr. C. D. Langworthy of Claygate sent fruits of *Fremontia californica* from his Claygate garden, where it is growing on a clay soil.

Bulbs in Grass.—As there are a number of small bulbous plants that look very beautiful

when naturalised in the grass, we would remind our readers that now is a good time to plant them. Chionodoxas, Scillas, Muscaris, Crocuses and Snowdrops are a few kinds which can be purchased cheaply and will, during the early spring months, brighten up such parts of the garden as would otherwise be uninteresting.

Album of a Famous Rosary.—The eminent rosarian, M. Jules Gravereaux of L'Hay, has just published an album of his famous rosary at that

Scotland, for £100 in name of loss caused by the death of a horse alleged to be due to eating leaves from a Yew. The action was raised by a farmer whose fields adjoin the churchyard, a Yew in which overhung one of them. The case has now been settled by defenders paying a sum of £60 and expenses.

The Quince Crop.—The common Quince is fast swelling up a good crop of fruits in this district, and unless very unkind weather visits us during October they should be of fine quality, the warm September having suited them admirably. The fruit is but little sought for as dessert, although quite recently a reverend gentleman told me it was simply grand; it was so distinct. The latter point I readily admitted, but otherwise we were not long in unison over its dessert qualities. However, as a preserve, either in the form of jelly or marmalade, it is to be welcomed, and to those who care for its peculiar flavour, just a "seasoning" among Apples used in pastry gives quite an added briskness.—H. TURNER, *Bawtry*.

A Chinese Rose with Attractive Fruits.—*Rosa sertata* is a new species from China of outstanding merit. Forming a large bush some 4 feet or 5 feet high, the long, elegant growths, clothed with glaucous or grey green, attract attention. In June the warm rose coloured flowers are pleasing, these being followed in autumn by deep red fruits. As they hang on the bushes at the present time, *Rosa sertata*, by reason of its graceful habit, soon attracts attention. This Rose was introduced by Mr. E. H. Wilson in 1907 from Central China, and is figured in the *Botanical Magazine*, t. 8473.

Geum Mrs. Bradshaw.—Once again this variety has proved its worth in the flower border, and it must be admitted that it is quite one of the best introductions of late years among hardy perennials. A decided point in its

place. An account of it from his own pen appeared in last year's "Rose Annual," issued by the National Rose Society. The receipts from the sale of this album will go towards the monument to be erected in honour of the young men of L'Hay who have fallen in the war.

Scottish Lawsuit over Poisoning by Eating Yew Leaves.—An action was brought recently against the minister and kirk session and the heritors of the parish of Girthon, in the South of

favour is its great usefulness in the mixed border, or the planting of it *en masse* for a bold display in the summer bedding scheme. A really bright and harmonious bed may be made by using the Geum as a carpet and relieving it with *Lilium tigrinum*. It may perhaps be useful to mention that the Geum does splendidly in pots, and really useful decorative plants may be obtained in pots 5 inches and 6 inches across.

A GRAND BASKET OF APPLE WELLINGTON SHOWN AT THE ROYAL HORTICULTURAL SOCIETY'S RECENT EXHIBITION OF BRITISH-GROWN FRUIT.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Little-Known British Bartsias.—With reference to the remarks in your issue of September 25, page 468, on the white variety of *Bartsia Odontites*, I may say that I do not think it can be, as suggested, of very rare occurrence, as I have found it quite often in Devon, and in more than one spot in the neighbourhood of Padstow, Cornwall. One patch in particular I remember, growing at the side of a field, was very large and fine flowered. It was also my luck to make the acquaintance of the yellow Viscid *Bartsia* (*B. viscosa*) in Cornwall this year, described by Sowerby as "one of our rarest plants," found chiefly in Devon and Cornwall and in Argyllshire. It was growing in great

for these fascinating flowers. Who can see Marigolds and Rosemary and not think of Shakespeare's Perdita and her "flowers of middle summer"? And what of all the many flowers mentioned by Keats and many another poet? Think, too, of all the legends and folk-lore interwoven in the garden—the dove and Olive branch, the crown of Bay, the Parsley crown, and the homely housewife's Lavender and herbs.—ANNE AMATEUR.

Covered Chains for Roses.—The invention mentioned by "West Country" in the issue of THE GARDEN for October 2, page 480, seems to me an admirable one. I am well aware that chains are often used without any covering except paint, and I believe they are so used at Kew Gardens, but in my opinion something, such as Bamboo sections to place between the iron and the growth of the Rose, is a great advantage. Personally, I would dispense

when they cannot be tied up closely, as is the case when chains are used.—C. G. B.

— Having seen Roses in great variety growing on chains without in the least suffering thereby, I cannot think the iron directly responsible for any ill effects. An instance of climbing Roses failing to give satisfaction once came under my notice. The failure was at first attributed to the iron supports on which the plants were growing. Further investigation, however, revealed the fact that other Roses trained on walls were also in the same unsatisfactory condition. An examination of the subsoil proved that there was a complete absence of drainage, and, of course, the roots were dead, or dying by degrees. There is a risk if tender shoots are secured too tightly, especially if string is used.—C. RUSE.

Sternbergia lutea in Scotland.—It was a pleasure to an admirer of the Sternbergias to read the excellent article on *Sternbergia lutea* in THE GARDEN of October 2, page 481. It is one of the most interesting and practical of the contributions which have been made on this charming bulbous plant, and should induce many who have not yet attempted to cultivate the alleged "Lily of the Field" to grow it. I may, perhaps, be permitted to refer to the point of shyness of flowering mentioned by the writer of the article in question. It does not present itself as a problem of so much consequence to the cultivator in the warmer South as in the colder Midlands and North of England and practically the whole of Scotland, where it is a great bar to the more general cultivation of the *Sternbergia*. In many places there it is hopeless to expect *S. lutea* to flower at all well. Personally, I am inclined to attribute this to the lack of heat in summer to ripen the bulbs properly, but it is sometimes said to be due to the premature decay of the foliage caused by early frosts in autumn. I have found the same difficulty with *S. macrantha*, however, and this produces its leaves much earlier—before the flowers—and premature decay of the foliage may in this case be ruled out of court. *S. macrantha*, by the way, appears, as your contributor remarks, to be possibly less hardy than some. It is extremely fine, but I have never been able to keep it for any length of time in the open. Of the forms of *S. lutea*, I have found *S. angustifolia* the freest bloomer, and my best results with it were obtained by planting in a warm, sunny, sheltered place, and by mixing some lime rubbish with the soil. It is so beautiful that one would gladly plant it more largely, but its irregularity of flowering is a great drawback, and it is galling to see its leaves appear year after year without any blooms accompanying them. The *Sternbergias* are so beautiful that those who can should attempt them at least. If successful in flowering them annually, the reward will be great, and a perusal of the article referred to will be well repaid.—S. ARNOTT, *Dumfries*.

Ixoras.—The magnificent group of *Ixora coccinea* from Warter Priory which was shown at the meeting of the Royal Horticultural Society on September 28 was greatly admired. Certainly never before has such an exhibit been seen at the Hall, for *Ixoras* have long rested under a cloud. Time was when they were extensively grown in gardens, especially in the days when specimen plants were popular, for no collection was considered complete without a liberal percentage of the best *Ixoras*. A fact perhaps not sufficiently recognised is that neat flowering examples may be grown in pots from 5 inches in diameter upwards. Their cultural requirements are not

TEA RAMBLER GROWING SUCCESSFULLY
OVER WELL-PAINTED IRON CHAINS.

with chain altogether and use instead stout rope, such as that employed by fishermen. This lasts a good long time, and when the Rose growths are well developed they practically support each other. The same objection to bare iron or wirework holds good with trainers for weeping Roses, also for stem supports for standards, and here is an opportunity for some up-to-date sundriesman to supply the necessary article. I should now like to point out the very great harm that follows the use of wired labels to Rose plants. I refer to those that are fastened on the branches. I have frequently found such branches quite dead after a severe winter, and whether it is owing to the action of frost on the copper or zinc wire I cannot say. I would advise all Rose-growers to banish such labels, or, if they employ them, to use aluminium wire or tarred twine. Perhaps some Rose amateur will favour us with his experience, for I have found it is from the amateur that we specialists often receive most valuable hints.—WALTER EASLEA, *Eastwood, Leigh-on-Sea*.

— I would like to mention that I have found new tarred rope about 1½ inches or 2 inches in circumference the best thing for training Roses upon between poles. Chains of iron are bound to get very hot in the sun and cold in frost, and so the wood of Roses suffers. Rope does not vary very much, and so the Roses can be tied quite close to it; they will not blow about in high winds and fray through the tie, which so often happens

profusion and luxuriance in marshy land. I hope these remarks may be of interest to your correspondent.—E. M. DUNN, *Tor Bryan Rectory, Newton Abbot*.

Garden Literature.—As I am in the midst of the miseries of "moving house," I have not read THE GARDEN very carefully just recently, but a note on garden literature by "Hurstcot," issue October 2, page 480, caught my attention, though I missed that of "C. H. S., Alderley Edge." Apparently the latter is one of those of whom Wordsworth wrote

"A Primrose by the river's brim

A yellow Primrose was to him,

And it was nothing more"

if he asserted "the garden appeals only through the eye." Mine appeals to the nose also, not to mention imagination and memory. When a Daffodil I see, I think of the poets in the spacious days of Good Queen Bess. Tulips recall Holland and the extraordinary mania that raged there

at all exacting, for cuttings of the half-ripened shoots root without difficulty if put into well-drained pots of peat and sand and plunged in a close propagating-case where there is a gentle bottom-heat. If stopped freely during their earlier stages, they form good, bushy plants that will flower profusely. Established specimens should be repotted when necessary during the latter part of February, at which time the roots commence to be active. A suitable compost may be made up of equal parts of loam and peat, with a good sprinkling of silver sand, and, in the case of large specimens, a few nodules of charcoal. No fewer than nine *Ixoras* were given first-class certificates by the Royal Horticultural Society between the years 1867 and 1891, but only one has been honoured since, and that obtained an award of merit in 1905. *Ixoras* are readily crossed, and the seedlings flower freely in a comparatively small state.—H. P.

NATURE - LORE.

In October, 1913.

We cannot hope to vend our verses now,
Unless they treat of insects, birds, or flowers;
A thought which corrugates the brainless brow
Of one poor scribbler, fond of fireside hours.

Myself, I rarely take these country walks;
And if I do the birds will not converse
As I go by; with me no blossom talks;
No insect-wonders dialogues rehearse.

In October, 1915.

Yes, they were hard at work two years ago,
Successful scribblers versed in Nature-lore.
They're at it still, as weary censors know.
How far seems Fleet Street from that dug-out's
floor!

They've watched the moths alight on Belgian
grass;
Heard song-birds courting all round Sixty Hill.
Their rhymes (omitting place-names) always pass;
Their Editors compete to show good-will.

Flowers? Ah, believe me, they don't write on
those!
When they see flowers, it's where thoughts lie
too deep
For scribblers' rhymes, . . . where multi-
lingual prose
Tells friends and kinsfolk, briefly, *where to weep.*
MABEL GARLAND.

The "Daily Mail" Show of Vegetables.—I am quite in agreement with your correspondent, Mr. F. Herbert Chapman, in your issue of October 2, page 480, in his various remarks as to the above show. It was truly a wonderful exhibition of kitchen garden produce, the like of which it is safe to say has never before been seen in this or any other country; but I am bound to admit that from a spectator's point of view it was disappointing in the extreme, and as none of the items was labelled, it was a bitter disappointment to many. Had these been properly arranged, as they unquestionably should have been, it would have made all the difference from the point of view of the public. No doubt the authorities were seriously handicapped owing to lack of space, as it was originally intended to hold the show at Olympia; but even in spite of that fact, there was a wealth of splendid material to have made an imposing exhibition. Showing

the produce in boxes was a serious mistake. Had this all been arranged by competent persons on slightly slanting boards, with suitable decorative and foliage plants through the centre, I am convinced a pleasing effect could have been made. E. B.

—Mr. Chapman, in commenting on the *Daily Mail* Show of Vegetables, said he came away with mixed feelings. "Great cry and little wool" was the thought that came to me after reading the report of the show and the great talk of increasing the nation's food supply. Our society has held a most successful show for the last twenty years. This season we dropped it. The reason given to our subscribers in a circular sent to each one was this: That the growing of show produce was incompatible with getting the most out of the ground. We, however, offered prizes to those who had cropped their ground the closest. Between fifty and sixty plots were judged. All were good, there being

The seed was sown of twenty-one of the best varieties, of medium height, on January 22, raised in a slight heat, pricked out into boxes when quite small, placed near the glass in a temperature of about 50°, properly hardened off, and planted out in the middle of April on a piece of ground 66 feet long and 36 feet in width, allowing a distance of 15 inches between the rows and 12 inches from plant to plant, and keeping them in their varieties. These were neatly staked, and the wealth of colour they gave when at their best was dazzling. By keeping the seed-pods removed, the plants continue to flower till quite late in the autumn. At the time of writing (October 2) the plants are quite gay. The varieties came practically true from seed, and I enclose a photograph of them, which I hope can be reproduced.—EDWIN BECKETT, *Aldenham*.

Ixias for the Rock Garden.—The note by "H. P." on page 486, issue October 2, draws attention to the usefulness of *Ixias* for the embellish-

SEEDLING ANTIRRHINUMS AT ALDENHAM HOUSE GARDENS.

only 1½ points between the first and second prize-winners. These plots were crammed from top to bottom with all that is necessary for a working man's household. The committee are satisfied that their object, namely, intensive culture, has been achieved.—JAMES SMITH, *Hon. Secretary, Harrow and Roxeth Allotment Society.*

Antirrhinums as Bedding Plants.—I am entirely in agreement with the remarks of your various correspondents in relation to these as summer bedding plants. I was first impressed with their value a year or two ago, when an extensive trial was made at the Royal Horticultural Society's Gardens, Wisley. Seen on a fine day as I saw them and about at their best, few things could be more beautiful. Though I have had a warm regard for *Antirrhinums* from my childhood days, and have grown them more or less ever since, this is the first year that I have attempted to seriously cultivate them, and my ambition has been more than realised.

ment of the greenhouse. Some of your readers may be interested to know that they can be grown with success in the rock garden, where they look particularly well, their slender stems, with brilliant coloured flowers, rising above the carpeting plants. As it is very cold here (Birmingham) and we are liable to hard frosts, I bury the bulbs 2 inches to 3 inches deep, and under a carpeting plant, such as *Hutchinsia alpina*, or, if in the open ground, give a little straw protection. I find they do not give very satisfactory results the second year, but as they are so very cheap, it is well worth while to plant a few fresh bulbs every October.—H. E. I.

FORTHCOMING EVENT.

October 18.—Royal Botanic Society of London
Lecture by Professor H. B. Bottomley on "The Discovery of Auximones," 4 p.m. Fellows' Rooms, Royal Botanic Gardens, Regent's Park, N.W.

THE ROSES OF AUTUMN.

JUNE, with its brilliant days and plethora of floral beauty, has so long and so often been quoted as the month of Roses that the layman may well be pardoned for looking upon it as such. Nor is he entirely wrong in doing so, because the majority of our Roses, especially in an early summer such as the past undoubtedly was, unfold the first of their blossoms at that time. But in modern Rose-growing these early blossoms are regarded as but the forerunners, the advance guard as it were, of the great floral pageant that is to come, and which is to extend into October, or, indeed, in some green years, well into December, before the stragglers from the rearguard bow their heads in winter sleep. Time was, and not so very far distant, when such a prolonged display would have been thought impossible. Twenty years ago the end of July indicated, to all intents and purposes, in Southern Counties, the completion of the Rose season, the few flowers that opened on some of the Hybrid Perpetuals and Teas after that date being looked upon as of little account, and certainly not worthy of taking into consideration when planning gardens for autumn effect.

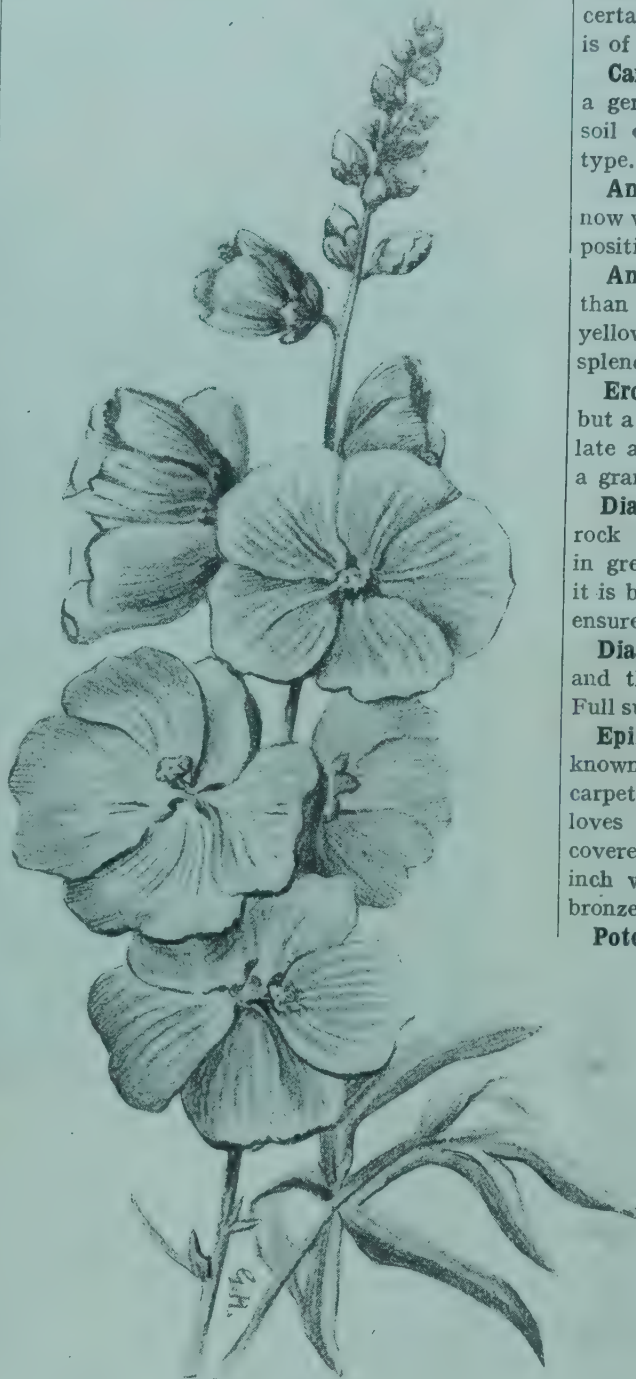

Thanks to the labours of hybridists in this and other countries, all this has been changed, and the Roses of autumn are rightly regarded as a feature of the garden during the waning months, when they are even more highly appreciated than their more fulsome though more fleeting brethren that open in the heyday of summer. Until the last six years the Hybrid Tea and Hybrid Musk Roses were the two families that we had to almost rely upon for autumn blooms, and even now they form the bulk of the Roses that flood our gardens with colour and fragrance at this season; but there is another race, and one that is rapidly growing, that must be taken into account. This is the set known as Pernetiana Hybrids, which embraces such varieties as Lyon, Arthur R. Goodwin, the brilliant yellow Rayon d'Or, and others.

It may, perhaps, be useful to give the names of some of the best autumn-flowering Roses, as a guide to those who may contemplate planting in the near future. All are bush or standard Roses except where indicated: Aimée Vibert, white, climbing; Antoine Rivoire, cream; Arthur R. Goodwin, buff yellow; Bouquet d'Or, buff, climbing; Camoens, deep rose and yellow; Caroline Testout, pink; Comtesse du Cayla, nasturtium red; Countess of Derby, peach; Duchess of Wellington, saffron yellow; Ecarlate, scarlet; Snow Queen, white; George C. Waud, crimson, suffused orange; General Macarthur, light crimson; General Schablikine, rosy salmon; Gloire de Dijon, buff, climber; G. Nabonnand, pink, shaded rose; Grüss an Teplitz, bright crimson, pillar; Gustav Grunerwald, carmine pink; Gustave Regis, nankeen yellow; Harry Kirk, pale yellow; Hugh Dickson, crimson, pillar; Jessie, bright crimson, Polyantha; Lady Alice Stanley, silvery pink, with rose reverse to petals; Lady Ashtown, deep pink; Lady Hillingdon, orange yellow; La France, pink; Lady Pirrie, coppery salmon; La Tosca, pale rose; Leonie Lamesch, coppery red, Polyantha; Longworth Rambler, bright crimson, climbing; Lyon, salmon pink and yellow; Miss Cynthia Forde, silvery pink; Mme. Abel Chatenay, salmon pink; Mme. Eugène Resal, coppery rose; Mme. Ravary,

pale orange; Mrs. John Laing, pink; Rayon d'Or, bright yellow; Richmond, crimson; Viscountess Folkestone, creamy white and pink; and Warrior, crimson.

SIDALCEA CANDIDA.

A NATIVE of New Mexico, *Sidalcea candida* is a hardy, handsome herbaceous perennial growing from 2 feet to 4 feet high, and bearing terminal racemes of large, pure white flowers. It is a very

AN AUTUMN-FLOWERING MALLOW. *SIDALCEA CANDIDA* ROSY GEM.

useful and ornamental plant for the herbaceous border, the wild garden or the shrubbery. At all times it should be planted in large masses; it then makes a very bold and attractive display. Even a bed of it in some secluded spot, providing it is not too shady, produces a very fine effect when in bloom. The flowers of *Sidalcea candida* Rosy Gem are of a deep rose colour and very attractive. They are as large as a florin, and profusely borne on stems $3\frac{1}{2}$ feet high. It is without doubt an excellent autumn-flowering plant.

LATE-FLOWERING ALPINES

IHAVE often heard the complaint among alpine-lovers of the dulness and scarcity of flowers in their rock gardens during September, but by a careful selection of plants this can easily be avoided. For the use of those plant-lovers so disheartened I give a list of very showy alpine flowers now flowering profusely upon my rock garden.

Campanula haylodgensis (syn. *Profusion*).—This is now one mass of pale blue flowers, and is certainly one of the showiest of Bellflowers. It is of the easiest cultivation on any sunny ledge.

Campanula haylodgensis flore pleno is really a gem, and rather rare. It needs a very gritty soil or moraine, and is not so rampant as the type.

Antirrhinum sempervirens is very effective now with its pale cream flowers. It loves a vertical position or wall and full sun.

Antirrhinum Asarina is of coarser growth than the previous one. It is now covered with yellow flowers. It has a trailing habit and does splendidly as a wall plant.

Erodium corsicum.—A rather new introduction, but a perfect gem for its continuous flowering until late autumn. It bears clear rosy flowers, and is a grand acquisition for any sunny spot.

Dianthus Atkinsonii.—A grand and beautiful rock plant, with the deepest red flowers borne in great profusion. For the benefit of the plant it is best to stop it flowering in late autumn, to ensure a good growth for the following season.

Dianthus Napoleon III. is similar to the above, and the double flowers are of the same colour. Full sunny position and gritty soils suit them both.

Epilobium macropus.—A rare and little-known Willow Weed, but one of the best of carpeting plants for the moraine possible. It loves a half-shady position, and is profusely covered with clear white flowers about half an inch wide. These, standing slightly above the bronze foliage, are very effective this month.

Potentilla Tonguei.—This is unique among alpenes for its quaint and pretty colouring of the flowers, which is a combination of red and orange. It loves a sunny position in poor soil.

Felicia abyssinica.—A miniature shrub covered with blue, Daisy-like flowers, reminding one of *Bellis rotundifolia cærulescens*, but with much clearer sky blue flowers; it loves the hottest spot in the rock garden.

Sedum pulchellum.—The prettiest of the genus, I think. Its clear pink, starry-like inflorescences, about 4 inches wide, give a lovely patch of colour on the rockery in autumn.

Sedum spurium atropurpureum cannot be omitted from a list of late-flowering alpenes. It is by far the best red *Sedum* grown.

Sedum populifolium is a very distinct shrubby species about 9 inches in height, the flowers opening a pure white, changing to a delicate shade of pink.

Sedum middendorffianum.—A dainty plant with clear golden flowers and finely cut bronze foliage. All *Sedums* love full sun and gritty soil.

Convolvulus althæoides is particularly effective on the rockery now. The flowers are of a pale satiny pink, rising above finely cut, silvery foliage.

It is rather rampant in habit, and is an ideal wall plant for sunny positions.

Convolvulus mauritanicus is another pretty plant, having clear blue flowers. It is most effective as a wall plant.

Veronica corymbosa.—A very quaint and pretty plant. The usual spike of this Veronica seems to divide into about ten or so small ones, which rise and form a corymb, making it quite distinct among the Speedwells. It has dark blue flowers and loves full sun.

Samolus repens.—A damp position on the bottom of the moraine suits this dainty gem well. Its clear white flowers studded all over the brown foliage make it very effective.

Veronica canescens.—A very pretty plant for carpeting a sunny moraine. The best description would be the counterpart of *Arenaria balearica*, but covered with pale blue flowers.

Cheltenham.

E. C. BOWELL.

THE BURNING BUSH.

(*DICTAMNUS ALBUS*.)

THE *Fraxinella* or Burning Bush is a very old and popular inhabitant of our gardens, having been grown in this country for over 400 years. As a subject for the herbaceous border it is a beautiful and interesting plant, interesting on account of the volatile inflammable oil which is exuded from the flower-heads and

seed-capsules during the hot weather. If a light be applied in the dusk of a summer evening, the whole plant will be more or less enveloped in a bluish flame, which is, however, only of very short duration. The white-flowered form, which is the type of the species, makes a bushy plant from 2 feet to 3 feet high, with large flowers in terminal spikes well above the foliage during the month of June.

In the colour of its flowers the *Fraxinella* is very variable, one of the finest and largest forms being *D. a. purpureus*, or *caucasicus* as it is sometimes called. It grows in good soil about 4 feet high, with larger foliage and flowers varying in colour from light to deep purple. These plants flourish in any good garden soil or sunny position, but resent moving. After being transplanted they take a long time before commencing to grow freely, so that to have good, well-flowered plants it is necessary to leave them severely alone when established. For this reason it is an excellent subject for naturalising in open beds in the wild garden, where it may be left undisturbed for years.

When it is necessary to increase the stock, the plants may be lifted carefully in early spring and the rootstock parted, leaving several eyes to each piece. These should be replanted firmly, if possible, in the position they are intended to occupy permanently. Seeds are produced freely, and offer another means of increase. They germinate readily, and may either be grown on in pots till large enough to plant out or in nursery beds.

A HYBRID JAPANESE ROSE.

(*ROSA RUGOSA* × *R. MACROPHYLLA*.)

THE Japanese Rose (*Rosa rugosa*) hybridises readily with other species and varieties, as is seen by the number of varieties now in cultivation. The chief object in these crosses has been to obtain ornamental flowering plants, good examples of which we possess in Mrs. Anthony Waterer and Blanc Double de Coubert. The subject of this note is chiefly remarkable for its handsome fruits. Among the species and varieties of wild Roses, there are many which produce highly ornamental hips or fruits in autumn and winter. These vary in colour from light orange red to jet black.

As is only to be expected of hybrids, the seedlings vary in character. Two large specimens in the Rose collection at Kew in November last were laden with hips. In one the bush resembles more in habit that of *R. rugosa*, the female parent, while the other is about 6 feet in height, showing distinctly the characters of the male parent. The fruits are rather lighter in colour than those of the Japanese Rose, and are borne in large clusters of twelve to fifteen or more hips, which in many instances bear down the branches with their weight. Individually the fruits are 1 inch to 1½ inches in length and three-quarters of an inch in diameter. The persistent calyx often exceeds 1 inch in length. Bushes of this hybrid make attractive lawn specimens, or are suitable for planting as a hedge to the Rose garden and as groups in shrubberies.

A. O.

DICTAMNUS ALBUS, THE BURNING BUSH OR CANDLE PLANT, NATURALISED IN THE WILD GARDEN.

PLANTING A CARRIAGE DRIVE.

BY GERTRUDE JEKYLL.

IT is perhaps the better general rule in garden design that the planting just within the entrance gate, and from there to the house, should be kept green and quiet, as a more suitable introduction to a bright display of flowers in the garden proper; but no one can find fault with the feeling of gracious hospitality that prompts the planting of bright flowers as a cheering welcome to the visitor. A suggestion for such a planting in a belt on each side of the road is shown in the illustration. A wide grass verge is next to the road. There must necessarily be a good proportion of evergreen shrubs, so as to secure a well-clothed appearance in the winter months. There are, therefore, close to the entrance, groups of green Holly, enlivened by the silvery stems of Birches. Then follow Rhododendrons and common Junipers, with Pernettyas and Andromedas to the front, and beyond them Tamarisk, a beautiful shrub that is too much neglected in general planting. After a good stretch of groups of shrubs of green foliage, with suitable companions of deciduous habit, there comes a region where reddish colour, both of bloom and leaf, predominates. Here the foliage, if not itself red, is of that soft grey that either takes a pinkish tinge or that, by its natural tenderness, harmonises well with pink and reddish bloom; this will be Tamarisk, Retinospora and Rhus Cotinus. At the far end and on the opposite side the prospect is further varied by a glow of golden foliage and yellow bloom. The shrubs are planted in generous masses; the long-shaped drifts are important, especially where much of the planting is viewed from a distance; it joins one group in pleasantly with the next, and avoids the meaningless, spotty appearance so often seen. The position of any of the groups of shrubs can be taken as a

suggestion for a more extended planting of the same, or of shrubs of the same class, on the further or garden side; thus, the road background of Rhododendron and Juniper would have more of these and would form the back of a Rhododendron garden; while, further along, Arbutus, Tamarisk and Retinospora, also added to in number and disposition, would be an admirable background for clumps of Azalea, Kalmia and Heaths.

A LITTLE-KNOWN SOPHORA.

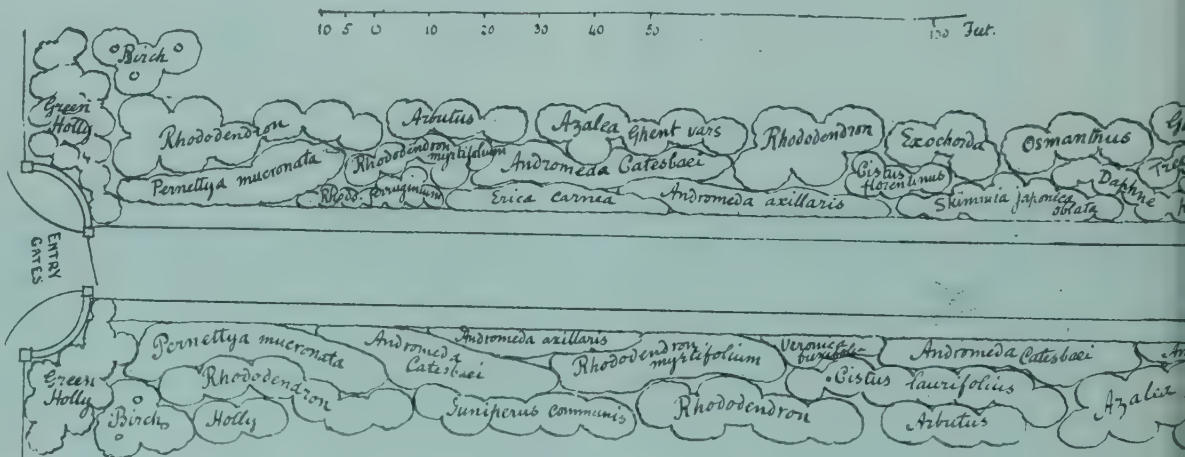

(S. VICIFOLIA.)

DURING the last twenty years many attractive trees and shrubs have been introduced to our gardens from China. Among these, Sophora viciifolia is one of the most valuable acquisitions. It is a deciduous shrub of elegant habit, some 4 feet to 6 feet high, or more when planted against a wall. The pinnate leaves give to the branches a light and graceful character. During June the branches are laden with short racemes of Pea-shaped blossoms, bluish white in colour, with violet or blue calyx lobes. A sunny position and a well-drained loamy soil are desirable for

the successful cultivation of this Sophora. Propagation is by seeds, which ripen freely on the bush illustrated. Until large enough for the permanent position, *S. viciifolia* should be cultivated in pots, as, except in a young state, it does not transplant readily. If necessary, the pots can be plunged in the ground, as is done with Ivies and Clematises in nurseries. In China the bushes grow wild over a wide area in Yunnan, Hupeh and Szechuan, and have been found at an elevation of 13,500 feet on the Tibet frontier. A. O.

THE TULIPS THAT FLOWER IN MAY.

OF all the hardy flowers that come to us in the heyday of springtime, few possess the quiet dignity and quaint charm that surround our May-flowering Tulip. As the bulbs of these ought to be planted not later than the end of October, and earlier if possible, no time ought to be lost in preparing the soil.

PLAN, SHOWING THE PLANTING.

THE FREE-FLOWERING SOPHORA VICIFOLIA AT KEW.

Deep and thorough digging is necessary, but manure, unless very thoroughly decayed, ought not to be added. A good handful of bone-meal to each square yard, scattered on the surface and lightly forked in after digging is completed, will be much better. Four inches is a good depth to plant the bulbs. These late Tulips must not be thought of in conjunction with the early, fugacious kinds that the maker of formal beds uses so religiously, but as flowers apart from all others for grouping in masses of one colour in the herbaceous border, in large beds, or, indeed, in any moderately open situation where bold flowers of good and distinct colours are appreciated. Arranged in this way under young Apple trees they create a glorious effect, the Apple blossom opening at the same time as the Tulips. While the Daffodil is creating bold splashes of gold and white in the garden, our late Tulips do not command much attention; it is only

when the first-named flowers have departed, and when there would be a hiatus in the outdoor display, that the full beauty and usefulness of the May Tulips are appreciated.

One emphasises the word usefulness advisedly, because these flowers are second to none for cutting, their long, sturdy stems enabling the veriest tyro to arrange them artistically in large bowls or jars, preferably those of plain, dull exteriors, such as the old Cornish pitchers. One of these loosely filled with a brown or mahogany-coloured Tulip, such as Dom Pedro, and placed so that white or cream wall-paper forms a background to the flowers, will give a picture of floral beauty that is scarcely obtainable in any other way. So varied and quaint are the colours to be found among these Tulips that they can be culled for all sorts of colour schemes. One of the prettiest effects the writer has ever seen was a large, plain Wedgwood blue vase filled with the common blue German Iris and the mauve lilac Darwin Tulip Rev. H. Ewbank, the sword-like foliage of the Iris forming the necessary garniture.

There are two main distinct types of May-flowering Tulips, one known as the Darwin, a comparatively modern race, the origin of which little is known except that they were raised in a Dutch nursery. The other is the Cottage Tulip,

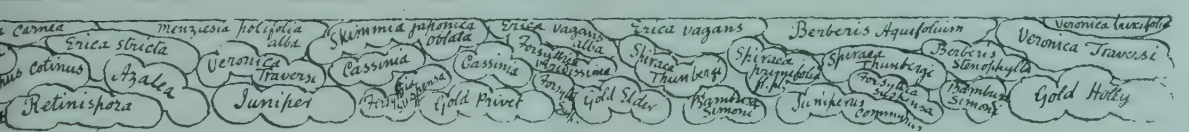

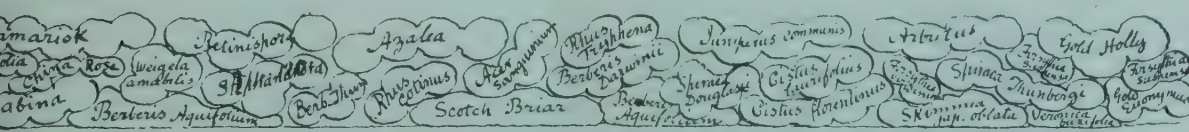

A BORDER OF MAY-FLOWERING TULIPS IN A READER'S GARDEN.

Erguste are two lilac mauve varieties with which I will close my limited list. F.

AUTUMN-FLOWERING BULBS FOR THE ROCK GARDEN.

NUMBERS of bulbous plants and others not belonging to the same great natural division, but which root from tubers or corms, are more fitted for a rock garden than for miscellaneous borders, where, almost unavoidably, they get overgrown and lost. The time has come when we should make notes from the catalogues of some of the more desirable of these for this special position. Too often we forget that provision has to be made at this season for the year to come, and only wake up to the oversight when we see delectable plants in flower in some garden not our own. To recall for a moment some autumn-flowering bulbs, nothing can be more brilliant in late August and September than the Mexican Tigridias; but they are seldom met with, being more often than not killed by over-kindness. Yet they are perfectly easy to manage, so far as the writer's experience goes, in any of the more Southern Counties. In planting, the growing point of the bulb should be not less than 4 inches below the surface, and sandy loam mixed with leaf-mould suits the requirements of Tigridias well. On obtaining new bulbs in the autumn, it may be a wise precaution to pot them rather than to plant out of doors at once, keeping them fairly dry and safe from frost, but in a cool place where they will not be incited to start prematurely. In April they may be turned into their permanent quarters outside, the planter being careful not to disturb any root growth which may have begun. Established clumps may be left in the ground during the winter, provided the soil is of a dry and porous nature, though it is safer then to give them a good covering of ashes. Like most bulbs, Tigridias

CARRIAGE DRIVE BORDERS.

so called because the bulk of the varieties that it embraces have been rescued from cottage gardens during the last fifty years or so. Many of these Cottage Tulips have been found in out-of-the-way places in Ireland, and no little romance attaches to the discovery of some. Both sections include some particularly fine varieties, which, as already stated, are exceedingly useful both for cutting and creating beautiful effects in the garden. The charge has been laid against them that they flower too late to enable the gardener to fill in summer and autumn the spaces that the Tulips now occupy. Where the ordinary bedding plants are relied upon, this is, no doubt, a drawback, but there are a great many other beautiful plants that can be utilised, particularly where the Tulips are planted, as they should be, in bold groups in the mixed border or in beds where a formal effect is not desired.

The varieties of late Tulips are now exceedingly numerous, and no two persons will agree on the merits of all. Thus, in making a selection, individual taste must, of necessity, play a leading part. I must confess to a partiality for those of orange, lilac, violet and maroon colours respectively; but a lady friend, who is by no means a bad judge of colours, cannot tolerate the violet Tulips. However, I will name a few that are my favourites, though some of them are not

regarded as good Tulips by experts. First must come Dom Pedro, a noble Tulip of rich red-brown hue, the interior of the petals resembling polished mahogany. Somewhat similar, but rather later in flowering, is Nigrette. Faust is a beautiful rich maroon Darwin that ought to be in every garden. Velvet King is a beautiful dark purple; and for a good lighter purple, one would select The Bishop, a stately Tulip whose dignity is quite in keeping with its name. Viola is a tall variety of graceful habit, the deep violet petals being slightly suffused with rose, and Mrs. Potter Palmer has flowers of soft rose purple. Among reds, King Harold, with deep crimson flowers, is a favourite; it invariably does well and has stout stems that withstand winds well. Orange King is a beautiful orange scarlet; Cassandra, rose; and Mrs. W. O. Wolseley, scarlet. Moonlight is a delightful yellow variety, with long flowers; and Golden Crown, a sturdy-looking plant, is also good. Among what may be termed fancy shades, there are a great many beautiful Tulips to select from. Clio, biscuit brown; Apricot, a very beautiful shade of that colour; The Fawn, pale fawn; Clara Butt, pale pink, flushed deep flesh colour; Quaintness, coppery orange; Fairy Queen, interior old gold, exterior flushed rose; and Beauty of Bath, pale lemon and mauve, are all worthy of a place in the best of gardens. The Rev. H. Ewbank and

require plenty of moisture during the growing season, with complete rest and moderate dryness after flowering. When the leaves turn yellow, they are ready for their mound of ashes. In a garden where this plan does not succeed, it may be better to give up their culture, as taking up and storing the bulbs through the winter months seldom answers well. There are several varieties of *T. Pavonia*, and the white forms with their rich crimson-spotted cups, though possibly a little more tender than the type, are supremely beautiful. Though all are but flowers of a day, a fresh one opens each morning, and thus their blooming is prolonged for some time. As the flowering stems do not exceed 12 inches in height, *Tigridias* are ideal bulbs for planting in sheltered, level positions in the rock garden, a little removed from the clashing autumn colouring of the herbaceous borders, where their brilliant orange and scarlet tints are not wanted.

Has anyone thought of trying *Belladonna Lilies* in the rock garden? In most gardening directions

species has the character of coming up in unexpected places and not keeping to its own quarters; but whether straying or no, it is never unwelcome. There are several autumn-flowering *Crocuses*, and the rock garden is the spot where they can be seen to greatest advantage and are best preserved from disaster. Of these, besides the one already named, three others may be specially noted, viz., *C. byzantinus*, with some superficial likeness to an *Iris*, hence sometimes met with under the name of *C. iridiflorus*—a large purple flower with paler and smaller inner segments and purple stigmata, a very beautiful species; *C. pulchellus*, varying in colour from blue lilac to white, free-growing and easily increased; and *C. zonatus*, a small kind, the rosy lilac flowers of which are distinguished by an orange base or zone. All of these are charming, flowering in September and October. There are also some white-flowered species, more or less veined, such as *C. cancellatus* and *C. hadriaticus*, which are well worth growing; nor do these exhaust the list. None of them is

Known to gardeners for nearly a century—the species was introduced from Brazil in 1827—it is possessed of a greater degree of hardiness than many imagine, and in favoured counties may be said to be fairly hardy, if not absolutely so. In other districts the plant may be wintered in a cold frame with comparative ease. In any case, even though a certain protection were necessary, it merits attention by reason of the brilliance of its scarlet flowers, the profusion with which they are borne, and generally easy cultivation. E. H. J.

THE DELPHINIUMS OR PERENNIAL LARKSPURS.

FOR creating bold effects in the outdoor garden, the stately *Delphiniums* or perennial *Larkspurs* are unsurpassed. Ranging as they do in height from 3 feet to more than twice that stature, according to the soil and variety, they can easily be accommodated in beds or borders, or any other positions that it may be necessary to fill. Good blue flowers are not too common—indeed, one might almost say that they are rather scarce—hence, we should make full use of these stately perennials, which embrace so many shades of blue. Fortunately, their cultivation does not call for any special skill. Good, generous diet, and attention to a few details that I will mention, are all that is necessary. Like every other plant that we undertake to grow, the *Delphiniums* well repay good cultivation, and for that reason the soil should be well and deeply dug, or, better still, trenched to a depth of 2 feet, and a liberal quantity of partially decayed manure thoroughly incorporated with it. Planting is best done in autumn, i.e., from the third week in September until the end of November, or during February and March, or the first week in April. For preference one would select autumn, as the plants then have an opportunity of becoming well established before flowering-time, which is usually June and July. As they are plants of goodly dimensions, overcrowding must not be tolerated, and from 2 feet to 3 feet apart is not too much space to allow.

The greatest enemy of *Delphiniums*, especially those that have been recently planted, is the ubiquitous slug. This insidious pest will, during the winter, scoop out the dormant shoots, and so ruin all prospects of flowers the following summer. It is important to remember this, because to it more failures can be attributed than to any other source. The remedy—a very simple one—is to cover each plant with a 2 inch thick layer of coal ashes early in the autumn, and see that it is well worked down between the stumps of the old flower-stems.

Summer treatment consists of supplying copious quantities of water during dry weather, supplementing it once or twice a week with weak liquid manure, particularly a few weeks before the flowers open. This makes a wonderful difference in the size, and often the colour, of the blossoms. A 2 inch thick mulching of short stable or farm-yard manure over the roots of the plants will also go a long way towards success, and is essential where the soil is at all sandy. It is not generally known that most *Delphiniums* will give a second display of flowers if properly treated. The *modus operandi* is to cut the flower-spikes down close to the ground as soon as the blossoms have faded,

THE BRILLIANT SCARLET VERBENA CHAMÆDRIFOLIA.

the indispensable condition for their culture" is said to be planting in the outside border of a hot-house or at the foot of a warm south wall, and no doubt these are excellent positions. But the *Belladonna Lily* is a denizen of the mountains, and, under natural conditions, has its bulbs wedged into crannies and crevices of the rocks, and sends its fibres into such crumbled granite, sand and scant peaty soil as can be found in such situations.

To come to less exacting subjects. It is when other plants are beginning to look fatigued and forlorn—all except the Mossy Saxifrages, which take on a fresher green from the chill night dews—that the autumn *Crocuses* will brighten any sunny nook we may have to give them. The best known, as also the first to appear, is *C. speciosus*, with large pencilled flowers of a fine blue-purple and showy orange stigmata—a veritable gem which comes to greet us unawares, so wedded together in our minds are *Crocuses* with spring. This

to be confused with the larger spring-flowering Dutch varieties, being mostly species from South Europe and Asia Minor, but they are cheap enough to be planted in some quantity. It is not a bad plan in the rock garden to carpet the surface of the autumn *Crocus* clumps with one of the small *Sedums*, *S. glaucum* or *S. Lydium*, as foliage is scanty when the flowers first spear through, and it serves to mark the spot as occupied. K. L. D.

LATE-FLOWERING VERBENA. (V. CHAMÆDRIFOLIA.)

DURING recent years hardy plant gardeners have brought this brilliantly flowered species into well-merited prominence by employing it more or less freely in rock wall, terrace and rock garden at the leading exhibitions, and probably many of our readers will recall seeing it at the Summer Show held this year at Holland Park.

then *thoroughly* water the plants, and as soon as new growth is active, feed well with weak liquid manure and renew the mulching. If watering is persisted in during dry weather, secondary flower-spikes will soon be formed, and, although not so large and stately as those that opened earlier, will, nevertheless, be very welcome in the autumn months.

The simple operation of staking is, of course, necessary, and is only referred to here because it is so often badly done, the flower-stems being trussed to a stake so that they form a passable caricature of a Birch broom. Miss Jekyll has adopted the most sensible plan that I know, and one that preserves the natural contour of the plants. Her method is to use natural sticks, such as are usually employed for supporting Peas, three or more of these being thrust in to each plant so that the shoots can push their way up between the branches. Very little tying is necessary, and the effect is excellent.

Delphiniums from Seeds.—

Although there are a great many named varieties listed in catalogues, a packet of seed purchased from a first-class firm will give a quantity of plants that are not very inferior, and which, for ordinary purposes, answer quite well. The seedlings are not difficult to raise. The best plan is to sow the seed in shallow, well-drained boxes or pans of sandy soil during April, May or early June, and place them in a cool greenhouse or frame. When an inch or 2 inches high they must be transplanted to a bed of finely pulverised and well enriched soil, where, by the autumn, they will have made sturdy young plants that will give some good flowers the following May or June, though not so large as may be expected another year hence.

The following are some good named varieties that are not too expensive for general planting:

Belladonna.—An old variety with sky blue flowers, which are produced very abundantly. Height, 3 feet.

Christine Kelway.—A tall variety with sky blue flowers and white eye. Considered by many to be an improvement on Belladonna.

Langport Blue.—This is a fine variety, 5 feet or more in height. Flowers rich bright blue.

Persimmon.—One of the prettiest of all. The flowers are clear sky blue, and are produced in abundance. The plant resembles Belladonna, but has a more robust constitution. Height, 3 feet.

Rev. W. Wilks.—Deep purple, flushed plum colour, with a prominent dark eye to each flower. A superb variety. Height, 4½ feet.

Sir George Newnes.—A semi-double variety with beautiful cobalt blue flowers, the inner petals flushed plum colour. Very effective when massed. Height, 4½ feet.

Sir Walter Scott.—Deep rich blue, flushed violet, with black eye or centre. Height, 4½ feet.

Althos.—Rich violet, flushed purple, with white centre. A charming variety. Height, 5 feet to 6 feet.

King of Delphiniums.—Semi-double flowers of rich gentian blue, flushed plum colour. Each has a white eye that renders the whole very attractive. A strong-growing variety. Height, 4½ feet.

True Blue.—Perhaps the richest coloured of all the Delphiniums, the flowers being pure intense blue. It has a good constitution and grows from 5 feet to 6 feet high.

General Baden-Powell.—Soft lavender, tinted rose, with a brownish black eye. A very restful colour in the garden. Height, 4½ feet.

James Kelway.—Very rich violet blue flowers, each with a pronounced white centre. Very effective when massed. Height, 5 feet to 6 feet.

BORDERS OF DELPHINIUMS AND FOXGLOVES IN A KITCHEN GARDEN.

Princess Maud.—Unique in colour, which is sky blue, veined rose pink, each flower having a white eye. It is semi-double and of fairly robust constitution. Height, 5½ feet.

Sir Trevor Lawrence.—Sky blue, with the inner petals flushed rose pink, white eye. Good constitution. Height, 6 feet.

Two varieties of more recent introduction, and consequently more expensive, are the Rev. E. Lascelles and Statuaire Rude. The first named has rich violet blue flowers, with a pronounced white eye. It is tall and very erect. The second is a very stately plant, the large spikes standing well above the foliage. The flowers are a charming shade of lavender blue, with a slight flush of rose.

A NEGLECTED VINE.

BY OWEN THOMAS, V.M.H.

[In Answer to a Correspondent.]

EVIDENTLY the Vine before it came into your possession had been over-cropped and otherwise neglected. Naturally, it will take some time to recover lost ground, although the recuperative power of the Vine is wonderful when given reasonable treatment.

In consequence of light cropping this year and the timely attention you have given to summer pruning, you may reasonably hope for better results next year. The cause of the cracking of the berries would, no doubt, be the blight contracted from the affected Beans and Tomatoes near by. This would prevent the outer cuticle (or skin) of the berries from expanding; hence the cracking.

The first essential in the successful culture of the Grape Vine is to secure an ample development of the shoots of the current year's growth, and of fruit buds thereon, as well as the perfect ripening of the same in autumn. It is these shoots which will produce the fruit of next year. "What, then," it may be asked, "are the essential points of good culture it is necessary to adopt in order to bring about the above desiderata?"

1. A well-drained border composed of the best Vine soil, care being taken to keep the same clear of weeds or any other robber crops. Efficient watering, and mulching with manure in summer to prevent drought. Removing the old top soil in autumn down to the roots, and replacing with a top-dressing of best Vine soil. Cover the border over in winter with fresh leaves to the depth of 10 inches, or with clean straw. Remove this at the end of April, and mulch with a layer of manure, 3 inches deep, as above.

2. Careful ventilation. Do not over or under ventilate; keep the atmosphere sweet and just nicely warm. Do not open the front ventilators until the month of April is out. Regulate the temperature by means of the top or back ventilators until then and avoid draughts.

3. See to the regular stopping of young lateral and sublateral

shoots during summer, to prevent the overcrowding of the Vine with useless foliage during summer.

4. Do not crop too heavily; more Vines are ruined by this cause than by any other. Far better have a few bunches of well-developed and perfectly-ripened Grapes than a plethora of diseased and sour fruit.

5. Thin the Grapes as soon as they are set.

6. Keep a moist growing atmosphere in the vinery during the season of growth by syringing the wall and floor twice a day.

7. Give abundance of air in autumn in favourable weather to ripen the wood, and where heat is available, apply it to the pipes in damp weather, with free admission of air for the same purpose.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Grapes.—Where there are only a few bunches hanging in a vinery, they should be cut and placed in bottles in the fruit room. The house can then be thrown wide open and any renovating of the borders done. Any Vines which have been cleared of their crops may be partly pruned, so that the ripening of the wood may be facilitated.

Plants Under Glass.

Humea elegans.—Much care is necessary in the culture of Humeas during the winter months, or many of the plants may be lost. Cool treatment is absolutely essential from now till the spring. Plants requiring a shift into larger pots should be attended to at once. Pot fairly firmly and do not overpot them.

Cannas.—The roots of these useful plants are often unduly shrivelled through storing them under the stages in a warm house. A cool frost-proof shed is the best place to store Cannas during the winter. The plants may be placed closely together and watered occasionally till the foliage has died right down. They may then be covered with straw or leaves.

Chrysanthemums.—There should be no difficulty now in keeping up a good supply of flowers, as plenty of the earlier-flowering varieties will now be coming into bloom. The late varieties must be kept outdoors as long as possible, but they must not be crowded together, or they will lose their foliage. Houses containing Chrysanthemums should be fumigated occasionally to kill aphides.

Eucharis.—Where the plants have been resting since completing their growth, a few may be placed in the stove to flower. The rest may follow at intervals to continue the supply of flowers. They must be thoroughly watered with tepid rain water, and when the spikes can be seen, give them plenty of stimulants. If mealy bug is present, sponge the leaves with strong soapy water.

The Flower Garden.

Planting Spring Flowers.—It is time now that the planting of all spring-flowering plants was commenced, so that they may become well established before severe weather sets in. The beds should be manured when digging, as this will save a considerable amount of work in the summer when other work is more pressing. Wallflowers, Polyanthus, Pansies, Forget-me-nots, Aubrietia, Double Arabis, Alyssum and Canterbury Bells may all be planted now. Let the work of planting be done as far as possible when the ground is in proper condition, so that the plants may be made quite firm.

Salvia patens.—This beautiful Salvia is often difficult to keep through the winter months. I have tried several methods of keeping it, and the one which has been most successful is that of lifting the tubers and placing them closely together in boxes, covering them with soil which is not too wet or too dry. They may then be placed in a frost-proof shed and kept quite dry.

Cannas.—Before these are lifted from the beds, see that they are carefully labelled. Only the very best varieties should be retained, as they are easily increased by division of the roots in the spring.

Fallen Leaves.—To facilitate the work of raking leaves, the long grass beneath trees should be cut before the bulk of the leaves have fallen. All leaves should be stored either for the making of hot-beds or to rot for making manure. Leaves falling on lawns must be kept regularly swept up, or worms will draw them into the ground, making the grass appear neglected. There will be little mowing needed on lawns after this date, but to give them a smart appearance the roller must be drawn over them occasionally.

The Hardy Fruit Garden.

Plums.—This has been almost a record season for Plums, and in many places I have heard that for market purposes the crop has not paid to gather. As is the case with almost all kinds of fruit, the

best sorts are always the most profitable to grow, and this must be borne in mind when buying new trees. For dessert, Early Transparent Gage, Green Gage, Denniston's Superb, Kirke's Blue, Jefferson's, Reine Claude de Bavay and Coe's Golden Drop are all excellent. For cooking, Belgian Purple, The Czar, Victoria, Pond's Seedling and Monarch are all good and reliable.

The Kitchen Garden.

Celery.—Disease has been very prevalent among Celery in this district, causing great damage to the earliest batches. Continue to earth up the later plants when the ground is suitable. In the absence of rain this crop must still be well watered.

Mushrooms.—From now till the spring, Mushrooms must be grown in a house where a temperature of 50° can be maintained without having recourse to much artificial heat. At no time must the hot-water pipes be heated to excess. Continue to collect the materials for making new beds, and prepare them in a dry shed.

Lettuce.—During very wet weather, Lettuce in cold frames should be protected by drawing on the lights. Forward plants out in the open may also be covered if lights are available. If frames are at command, there should be no difficulty in keeping up a supply of this useful salad all through the winter by putting out plants in various stages of growth.

Endive.—The most forward plants may be tied up. These should be ready for use in ten days or a fortnight. Later plants may be dug up with a good ball of roots and planted closely together in frames. Frames may also be placed over plants in the open ground.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Flower Garden.

Zonal Pelargoniums.—Where there may be a shortage of cuttings of any particular variety, the old plants should be lifted, partially stripped of their foliage and potted up in 4-inch pots. These plants will also be useful for the centres of large beds or vases where taller plants are required. Very little water will be necessary for them until spring.

Bedding Stock.—As frosts are now inevitable, it should be seen that all tender plants are housed where there is pipe heat or sufficient protection from frost and damp. Opportunity should be taken when removing them indoors to pick off bad and decayed foliage.

Tulips.—Both early and May flowering Tulips should be put into their places, if this has not already been attended to. If the bulbs are kept out of the soil too long, the flowers will not be nearly so fine. Darwin or May flowering Tulips should be planted at least 5 inches below the surface; they revel in rich soil which contains plenty of sand.

Crocuses and Snowdrops.—Where these are to be planted in grass—and they make a fine successional display in spring—a start should now be made, as they commence to emit roots at this season. Lifting back the turf where they are to be put is generally sufficient, if it is replaced carefully and then lightly rolled.

The Kitchen Garden.

Root Crops.—Any crops which may still be left should now be lifted, with the exception of Parsnips and Salsify. These two vegetables are quite hardy and are best allowed to remain where growing, unless the ground is needed for other crops. If possible, choose a fine day for the lifting and storing of Carrots and Beetroot.

Cabbage.—Any blanks which may have occurred among Cabbages which were planted out should now be made good. The largest weeds can then be cleared off, and the ground gone over with the Dutch hoe whenever the weather permits.

Lettuces.—Late-sown Lettuces can be pricked out at the base of a south wall, if such a site is

available. Here they will need no further protection, and if the winter and early spring should prove mild, they turn in very early and generally prove useful.

Seakale.—For very early supplies it is easy to buy retarded crowns, which force very easily and quickly. Either put them in a Mushroom house or place them in pots and cover with an inverted pot of the same size.

French Beans.—It should be quite easy to keep up a supply of this vegetable for some time yet from plants sown outdoors, if protected with frames previously. They must be covered up well when there is danger of frost, and sufficient ventilation kept on during the daytime to prevent the small Beans and leaves damping.

Plants Under Glass.

Violets.—If reasonably fine weather continues, the lights may remain off until severe frost or heavy rains compel them to be returned to the frames. The lights should not be closed except during severe weather. Want of ventilation is a common cause of failure with Violets.

Climbers.—In plant stoves, many of the climbers which have become a little overgrown should now be partly pruned and tied up, to encourage the ripening of the remaining growth and foliage. If this is delayed, the plants growing underneath might possibly suffer from the dense shade caused by the overhanging climbers. Insect pests are also more easily kept in check by attention to this.

Begonia Gloire de Lorraine and its varieties should now be allowed to develop their flowers, unless they are required for very late spring, in which case bud picking may continue for some time yet. As the flowers open, a slightly drier atmosphere should be maintained, but damping of the paths should continue at least once a day.

Hard-Wooded Plants for Forcing.—After all the bulbs have been potted up, these will next claim attention. Lilacs, Pyrus, Prunus, Azaleas, Deutzia, Viburnums and Hydrangea are all easily forced from the middle of December onwards. The Azaleas, Pyrus and Prunus succeed best in peaty soil. After potting, stand closely together outdoors and cover the pots with new leaves to protect them from frost. The plants themselves, however, should be fully exposed, as they respond to heat more freely after being subjected to frost.

The Hardy Fruit Garden.

Preparing Ground for Fruit Tree Planting. Where it has been decided to make any new plantations, either of trees or bushes, the ground must be well prepared in advance. The earlier it is done, the better condition it will be in for planting. Keeping in view that it will have to sustain the bushes or trees over a number of years, ample manure must be trenched in, both under the top and in the lower spits. Where the soil is known to be devoid of the essential plant foods, a sprinkling of bone-meal or other nourishment should be added as the work proceeds.

Fruit Under Glass.

Successional Trees.—Where the grower has not sufficient space at command to nurse young Nectarine and Peach trees for filling up possible blanks, caused by exhausted trees having to be discarded, some young ones should be purchased and planted outdoors, against a south wall for preference. These should now be planted, and later on trained carefully, where they will be of service in later years to take the place indoors of older trees.

Peaches and Nectarines.—The majority of the early trees are now fast dropping their leaves. Sometimes, for the sake of housing Chrysanthemums beneath them, they are removed prematurely. This practice cannot be too strongly condemned. Still, if the foliage is thoroughly ripe, no harm comes from removing the leaves, providing the buds are not injured during the operation. A light brush made of Birch twigs may be used if it is applied in the same direction as the branches of the trees are growing.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

NOTES ON KITCHEN GARDEN CROPS.

THE tropical heat experienced in many districts during the third week in September caused the crops of Autumn Giant and similar varieties of Cauliflower to run riot. Several in our own district started feeding pigs on specimens which, in the ordinary way, would have fetched threepence each. What a pity the growers did not adopt the plan, pretty general in many gardens, of digging these up when about three parts grown and laying the roots in damp soil with the heads facing north. A shady portion of a large wood often enables us to keep surplus heads in good condition for several weeks, while a cool, dark shed serves a useful purpose when these turn in too rapidly for immediate consumption. Small growers, please note. We have now reached the fringe of the season when choice vegetables are likely to be scarce, and quite one of the choicest among these is the Cauliflower.

Tomatoes in Pots.—When these are no longer on the active list, do not throw the soil on to the rubbish heap as worthless; there yet remains much that will help some other crop to make a good start in life. Certainly one of the best uses to which this can be put is, after being sifted, to store it in a dry shed, and next February use it for bedding the early Peas in, also for covering them after sowing. Failing this, use it when preparing the seed-bed for Brassicas. Whenever possible, let the bed of spring Cabbage contain more than one variety, as seasons count much with this crop. What did well last year may be quite out of the running—as far as early heads are concerned—next year, and as it is these we want, avoid failure by having more than one string to your bow. Several years ago I saw many thousands of Imperial, not a bolter among them; last year the reverse was the case. We grew half a dozen varieties; four were wise and two were foolish. Had we relied absolutely upon the two last, what then?

A Word to the Wise.—Inexperienced readers are warned against the folly, often indulged in at this season, of destroying August-sown beds of Turnips, simply because they have not bulbed as early as expected. The experience of the past twelve years proves there to be yet ample time for what at present appears to be only greens developing into useful Turnips before the end of November, and even should this not be the case, these tops may still be dug into the ground, where they will soon decay and form manure. Where beds of half-developed Lettuce are growing in such exposed positions as to cause doubt as to their ability to withstand a sharp snap, the grower is advised to choose the lesser evil, lifting each with a good ball of soil and replanting a foot away from a warm wall, watering well in. Parsley is in constant demand throughout the winter, and although it takes a very severe frost to kill it, risks should not be run; and in the event of heavy snow, it will be found that Parsley-hunting is not nearly the exciting sport many of us find fox-hunting to be. (In food, of course, Mr. Editor.) A few old rough boards, nailed together, make a very good temporary frame for this crop, needing but the covering of a few bushy sticks and sacks to prevent harm from the most severe frost. Parsley transplants quite safely now. Get well

down to the roots, burying these deeply in the new quarters, and always follow up the planting by giving a good watering.

Shortly after established beds of Seakale go to rest, *i.e.*, lose their large leaves, lift some of the most promising crowns and store them in a cool shed. Next month these may be brought into growth by introducing them to a heated house, and this not necessarily a glass one. A dark place in a warm kitchen will grow real good Seakale.

Grading Root Crops.—Where, at the time of lifting the various root crops it is usual to get into winter quarters before the close of the present month, the time of the grower permits it to be done, it will be an advantageous plan if, instead of mixing all the badly shaped, bruised, or undersized specimens of each and storing them together, these latter are put aside for present use, and only those stored away the condition of which shows them to be dependable for keeping over a period of many months, much unpleasantness and loss would be spared the grower.

To show the importance of this, it should be remembered that Parsnips showing signs of decay at the crown soon become worthless after being in the store. A single decayed Carrot is often directly responsible for the loss of many scores; while apart from the unpleasant smell arising from a single Onion which has lost its culinary value, its contaminating presence with sound bulbs cannot fail to have a detrimental effect upon what to most growers is a very important crop.

Feeding Leeks.—The advice to discontinue feeding, or applying stimulants, to growing crops after the end of this month does not apply to Leeks, for growers of large quantities of these will have noticed that, providing we get the usual mild autumns and early winters to which we have now become accustomed, the amount of new growth made by healthy plants of these, after what is termed the end of the growing season, is truly remarkable; and as nothing we cultivate is more hardy than this, and fewer supper dishes more generally acceptable, it goes without saying that, if it is within the power of the grower to accelerate the growth and increase the length of stem, it is wise for him to do so.

Speaking for ourselves, and having a very porous soil to deal with, we never think a thorough soaking with moderately strong liquid manure is out of season where this crop is concerned, a regular deluge being given to the soil between the rows in all save the most frosty weather, the result being I can commend the plan to others, particularly where the soil is light, or to those having soil which, at the time of planting the crop, lacked the addition of those valuable and sustaining food properties a liberal dressing of farm-yard manure assures.

The Way to Deal with Unripe Tomatoes.—Where plants in the open air still carry unripe fruits of these, it will no longer be safe to leave them exposed to certain ruin which a spell of bad weather assures; but if, instead of picking these fruits off close to the stem and laying them in boxes as sometimes advised—which invariably means considerable loss through decay, while others which remain usually become so badly shrivelled as to be of little use, save for soups, &c.—the grower is advised to cut away a good portion of the stem with the bunches, and hang these in a sunny window; here it will be found the fruits colour more quickly, retain their plump condition and good flavour for quite a long period, while the losses from decay will be nil.

F. R. CASTLE.

APPEAL TO COUNTRY PEOPLE.

THE following practical suggestions, among others, are issued by the Board of Agriculture and Fisheries Whitehall Place, London, S.W.:

Produce Food for Yourself!—Everyone who lives in the country or has a garden can produce something to eat—the more the better: vegetables, fruit, poultry, eggs, rabbits, milk, cheese. Plant at once what you can, and prepare in all possible ways for next year's cropping. Every plant in your garden may save you money! Produce all you can; buy as little as possible! Cultivate thoroughly! Destroy insect pests and weeds! Prepare manure!

Preserve and Store Your Crops with Care!—The finest harvesting may be rendered useless by bad storing. Protect from the weather! Destroy vermin! Store your own vegetables! Bottle your fruit or make jam or pulp of it! Preserve your eggs when abundant! Cure your own bacon! Eat little meat! Replace meat by milk, cheese, Peas, Beans and Lentils, which are as rich in flesh-formers as meat and much cheaper. Use more vegetables! Eat more fruit!

Cook Vegetables by Steaming!—Boiling in water reduces their food value! Cook Potatoes in their skins! Use the Hay-box Cooker; it will save coal.

Use Less Coal!—Burn wood, peat, &c., whenever possible!

Save Fodder!—Use Acorns, Chestnuts and beech-mast for stock; Bracken for litter; all suitable straw for fodder; fodder crops for pigs. Keep pigs, poultry or rabbits to eat up house refuse, damaged vegetables, light corn!

Waste Nothing!—Buy nothing from abroad that can be produced at home!

BRACKEN AS LITTER.

IN view of the present high cost of feeding stuffs, it is necessary that as much as possible of their manurial value should be recovered in the manure. The fact that the ordinary supplies of potash are meanwhile cut off furnishes another reason for preserving manure, especially liquid manure, with great care; liquid manure is rich in potash. In districts, therefore, where straw is scarce, or where it can be profitably fed to stock, farmers and horse-keepers should use for litter any other suitable material that may be available at a reasonable cost. Bracken or "Fern" is specially worthy of attention at the present time.

Bracken possesses considerable value as litter, and in many places it may be obtained for the cost of cutting and carting. Bracken harvested while still green usually contains as much phosphoric acid as straw, and much more nitrogen, but less potash. If exposed to rain throughout the winter, a considerable loss of substance is likely to result, although Bracken cut in April has been found, on analysis, to have a similar composition to straw.

Bracken possesses a considerable power of absorbing ammonia and urine. To secure the full absorptive effect, however, Bracken must be very thoroughly trampled upon by stock.

Manure made from Bracken may be expected to be equal in chemical composition to manure made from straw. On the other hand, it takes longer to decompose in the soil, the fibrous woody stem being only slowly attacked. It therefore opens up the soil more, and is for that reason likely to be more useful on a heavy clay than on a light, sandy soil. Bracken should be cut and dried in autumn.

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

VIOLA PRIMULÆFOLIA AND UNOPENED FLOWERS (E. B.).—The flowers that never open borne by the Violets are quite common in many species, and are known as cleistogamous flowers. They usually produce quite fertile seeds, and are formed, as a rule, in the later part of the year, after the normal flowers are over. The ordinary flowers of some Violets do not seed, or but rarely, and these cleistogamous flowers are formed for the purpose of ensuring seed production. Possibly removing the plants to a rather more open situation would induce them to flower in the spring.

PROPAGATING BULBS (Frances Mary Glossop).—Unfortunately, you omit to say to what class of bulbs you refer, but, assuming it to be the Daffodil, you could plant all the smaller divisions or offsets in a reserve plot or in a nursery bed in lines, where, in well-cultivated soil, they would be safe for two years at least. Arrange the bulbs an inch or 2 inches apart, the lines 9 inches or a foot asunder. If they are Tulips, a more sandy soil would be required, with annual lifting and resting. Should the above not apply, please write us again and say exactly to what bulbs you refer.

OXALIS ENNEAPHYLLA AND LINARIA (James Paterson).—It is very unusual for the Oxalis to be flowering so late and in the good condition to which you refer, and we are wondering whether it is the outcome and development of a spring planting or a second flowering. If the latter, it is more unusual still. The Linaria usually behaves like a biennial, unless it is in the poorest of soils, adjacent to rocks, or springing up in a gravel path, as it often does from self-sown seeds. In rock fissures it is often a good perennial, but in richer soils liable to die out quite suddenly. The Wulfenia delights in a cool nook in rather rich soil, and in such is quite tractable. We should consider soil poverty and dryness at the roots the chief reasons why the flowers did not develop. Try the plant in richer soil—peat, leaf-mould and loam equally—and in a cool or slightly moist place.

ROSE GARDEN.

ROOT-PRUNING ROSES (Rose).—Most certainly we should advise you to transplant the bushes. Whenever Roses appear to be declining in vigour, be they bushes or standards, they should be transplanted, and as early in October as the state of the soil will permit. You should have the plants dug up, all the foliage removed, and cut back hard any soft shoots. Prune the roots back fairly hard, preserving as many of the small fibrous roots as possible. Then put the plants in a trench, cover the roots well with soil, and give a good watering. If this trench is in the shade, so much the better. Proceed next to overhaul the Rose-beds, digging them 2 feet to 3 feet deep, and work into the lower soil good manure, basic slag, and any burnt garden refuse you may have. A little well-rotted manure may be mixed with the top foot of soil. After allowing the beds to settle down for about ten days, replant the Roses, giving each plant a handful of bone-flour just beneath the surface soil and well scattering it about. We thank you for your sympathetic reference to our late Editor, who always studied to the full extent of his power the best interests of readers.

MISCELLANEOUS.

INSECT ATTACKING LEAVES OF THE SWEET CHESTNUT (H. T.).—The Sweet Chestnut foliage is attacked by one of the leaf-mining caterpillars, which later become minute moths. We do not anticipate serious injury from the attack, nor do we think spraying would alleviate it. It would be well, if the trees are small, to collect the attacked leaves and burn them, as this would be likely to reduce the trouble another year.

SHORTAGE OF FARMYARD MANURE (S. O. R.).—We quite appreciate your difficulty in the shortage of farmyard manure, and with so many horses at the front there appears little likelihood of getting a supply for some time to come. We certainly cannot recommend the use of so-called radium manures. They have given negative results in experiments. As a substitute for farmyard manure you will find Wakeley's Hop Manure of good value. It is a natural manure specially treated with artificial fertilisers. It is concentrated, and needs only to be applied as a very light dressing.

NAMES OF PLANTS.—W. Hanna.—1, Aster Novi-Belgii Perry's Pink; 2, Aster Novæ-Angliæ, type probably—such things are almost impossible to name correctly from a solitary flower-head; 3, Aster Novæ-Angliæ roseus. There are several good firms in the county you name who could supply plants, though for modern sorts a specialist would be best.

NAMES OF FRUIT.—F. H. Bull.—1, Ecklinville; 2, Stamford Pippin.—H. J. S.—Apples: 1, Newton Wonder; 2 and 3, Hawthornden; 4, Lamb Abbey Pearmain; 5, Cellini. Pears: 1, Brown Beurré; 2, Easter Beurré; 3, Bergamotte Espéren; 4, Winter Nelis.—Pollo, Ross-shire.—1, Warner's King; 2, Withington Fillbasket; 3, Worcester Pearmain; 4, Beauty of Bath; 5, Ecklinville; 6, Lord Grosvenor; 7, Duchess of Oldenburg; 8, not included; 9, Yorkshire Beauty; 10, Christmas Pearmain; 11, Wyken Pippin; 12, Devonshire Quarrenden.

OBITUARY.

C. F. BALL.

MR. C. F. BALL, who in times of peace held the position of assistant keeper of the Royal Botanic Gardens, Glasnevin, Dublin, has, we are extremely sorry to learn, been killed in the Dardanelles. At the outbreak of war he joined the D (Pals) Company of the 7th Royal Dublin Fusiliers. A life full of promise and still in the vigour of youth has been given for his country and in the cause of justice. All honour to his memory. Four years ago, Mr. Ball, accompanied by the writer of these notes, journeyed to Bulgaria for the purpose of visiting the famous Rose garden of Europe, and to collect plants from the Balkan mountains and Rhodope Alps. He was a delightful companion, unassuming, sincere, and a most lovable man. Seldom did any plants of interest escape his

THE LATE C. F. BALL.

keen and well-trained eye. I well remember how, one day on the Shipka Pass, his face brightened with delight on finding the rare albino form of *Haberlea rhodopensis*. As the result of his travels Mr. Ball read a very interesting paper before the Royal Horticultural Society on the flora of Bulgaria and the Maritime Alps, illustrated by lantern slides prepared from many of his own photographs. Mr. Ball occasionally contributed notes to these pages on hardy plants at Glasnevin, and for the past five years he successfully edited *Irish Gardening*. For three and a half years he worked at Messrs. Barron and Son's, Elvaston, Derby, and he was later employed in Messrs. Barr and Sons' nursery at Long Ditton. He entered Kew in 1900, and left in 1906, after working in the rock garden and herbaceous grounds. He was immensely popular, and commanded a good deal of respect as an athlete as well as a student. His loss is made the more pathetic since he was married only a few months ago, and to his widow we extend our sincere and heartfelt sympathy.

SOCIETIES.

READING AND DISTRICT GARDENERS' ASSOCIATION.

THE first meeting of the autumn session was held on October 4 in the Abbey Hall (by kind permission of Messrs. Sutton and Sons), and was well attended. The president, Mr. F. B. Parfitt, presided, and was supported by the chairman and vice-chairman (Mr. H. Goodger, Stotham House Gardens, and Mr. E. Blackwell, Foxhill Gardens). The subject for the evening was "The Recent Visit to Bear Wood Gardens," and a very interesting discussion took place on many of the crops noticed, such as Grape Melons, Tomatoes, Peas growing under glass, and Caul flowers; also Sweet Peas in pots for flowering early in the season, and blight and silver-leaf on Plums. Much valuable information was given by Mr. J. T. Tubby, head-gardener, Bear Wood Gardens, in answering the various questions put by the members. Owing to the resignation of Mr. Lawrence Castle from the office of hon. secretary, Mr. H. G. Cox of 80, Hamilton Road has been appointed his successor.

GLASGOW AND WEST OF SCOTLAND HORTICULTURAL SOCIETY.

A LECTURE arranged by this society was held in the Religious Institution Rooms, Glasgow, on the evening of October 6. Mr. D. G. Purdie, chairman of directors, presided over a good attendance. The lecture of the evening was given by Mr. John Highgate, gardener to the Marquis of Linlithgow, Hopetoun House, South Queensferry. Mr. Highgate's subject was "The Use of Perennial Plants in the Embellishment of Present-day Gardens." It was dealt with in an exhaustive and attractive manner by Mr. Highgate, as may be expected from one who is doing such good work in this way in the noble gardens under his charge, where hardy perennials are utilised in a magnificent way. Mr. Highgate discussed his subject very fully, and gave many details regarding suitable plants, selecting for special prominence a number of effective and useful subjects of a bold character, as well as those of dwarf habit. Alpines were recommended for edgings. Mr. Highgate also strongly advocated the planting of flowers which would give a supply of bloom over as extended a period as possible. He spoke warmly in favour of planting in clumps. The lecture was illustrated by a number of excellent views. Mr. Highgate was heartily thanked.

NATIONAL SWEET PEA SOCIETY.

THE annual general meeting of this society was held on October 11 at the Royal Horticultural Society's Hall, Vincent Square, Westminster. The meeting was presided over by Mr. E. H. Christy, chairman of committee. From the report of the committee it is apparent that the war has seriously affected the society. Though eighty-three new members have joined, seventy actual resignations have been received, four gone away and three deceased, while many of the affiliated societies are unable to continue their membership, but two new ones have joined. Many subscriptions from members for 1915 are unpaid, but it is still hoped that some of these will come in.

The Trials were held as usual. Mr. Reginald W. Christy of Boyton Hall, Roxwell, near Chelmsford, was appointed Trials Superintendent, and grew the stocks there. The committee are to be congratulated on their choice, for a finer set of trials has never been grown for the society. The plants were healthy, robust and even, and not a weed was to be seen. Heartly thanks to Mr. Christy and his daughter, who has been his right hand, were enthusiastically expressed.

The Society's Roll of Honour.—Among those serving their King and country are many members of the society and the following members of the committee, viz., Captain Vernon T. Hill, Major Martin F. Hitchings, A. L. F. Cook, N. S. Thornton, B. Peyman and E. J. Gee. Among the fallen is Major Cautley D.S.O., who was killed in action.

Finance.—The report concludes: "Undoubtedly the war has had a great deal to do with the financial side of the society this year. We have had a great drop in the amount paid in for members' subscriptions. Last year we received £291 15s. 5d.; for 1915, £209 16s. 9d.; and from the affiliated societies the amount received in 1914 was £62 4s.; for 1915 we have only received £28 7s. These losses in themselves are a serious matter for the society. The gate money for the London show, 1915, was £13 5s. 6d. against £19 19s. in 1914. The committee recognised at the outset of the year that we might expect some falling off as a natural consequence of the critical times, and, in endeavouring to guard against this, economised in every department where it was possible, as the financial statement will show."

Election of Officers.—On the proposition of Mr. J. S. Brunton, seconded by Mr. A. Ireland, Mr. E. W. King was unanimously elected president for the ensuing year. Mr. J. S. Brunton was elected chairman, Mr. E. Sherwood re-elected treasurer, and Mr. H. D. Tigwell re-elected secretary of the society. The new members of the general committee are Messrs. A. C. Bartlett, Herbert Cowley, G. H. Burt and E. H. Christy. Messrs. R. Bolton, Carnforth, and J. Malcolm, Dunbar, were added to the provincial corresponding members of committee, while the following specialists comprise the new floral committee: Messrs. A. Ireland, T. Jones, G. H. Burt, T. Stevenson, T. A. Weston, E. H. Christy, C. H. Curtis, A. Malcolm and A. Hallam.

THE GARDEN.

No. 2292.—Vol. LXXIX.

OCTOBER 23, 1915.

NOTES OF THE WEEK.

New Rose Hadley.—The standard of the ideal Rose has been much advanced during the last decade. Roses which flower well in autumn are among the most popular, and Hadley proved its worth in this direction by securing the award of merit from the Royal Horticultural Society on September 28 for flowers cut in the open, when it was exhibited by Messrs. Stuart Low and Co. of Bush Hill Park. The photograph from which our illustration was prepared is of flowers cut during October. It is a strong grower, free flowering, and is, indeed, of stronger and improved Richmond habit. It is much deeper in colour, being of a maroon crimson shade, almost as dark as Château de Clos Vougeot. The illustration shows that Hadley has good form; if it could depict its perfume, it would be very sweet indeed. It has more of the Damask scent than is even found in the famous General Macarthur. It is a curious fact that many of our best forcing Roses have been discovered in America. Ophelia, for instance, a British-raised variety, was found to be a splendid forcer by growers in the United States. Hadley is a Rose which has also proved its worth as a fine variety for forcing in the same country.

An Effective Bedding Arrangement. A series of oblong beds in Princes Street Gardens, Edinburgh, have, during the past summer, had a very pleasing effect with the following arrangement: A groundwork of Viola Maggie Mott dotted with Centaurea ragusina and edged with Lobelia Waverley Blue, the whole being thinly dotted with a medium height dark Fuchsia and Lobelia cardinalis Queen Victoria.

Senecio Clivorum.—This is a most useful plant for massing in the wild garden, especially on the banks of pools or streams. It is easily raised from seed or by the division of old plants. When once established, seedlings will be found springing up wherever old plants have flowered. These may be dug up and replanted in suitable places, but it is a gross-feeding plant and needs a moist situation to grow it to perfection.

A Rare Oak.—*Quercus pontica*, the Armenian Oak, is a distinct-looking species from North-East Armenia and the Caucasus. The present habit of growth suggests that it is a large shrub or spreading tree of moderate height. It is deciduous and the leaves are large, being up to 7 inches in length and $3\frac{1}{2}$ inches broad at the widest part, on plants 3 feet in height. As an ornamental specimen tree

the Armenian Oak will doubtless prove of real value and interest for the lawn and pleasure grounds.

October Roses at Kew.—Owing to the mild autumn, the beds of Roses around the Palm House at Kew are still (October 18) exceptionally bright with blooms of good quality. Hybrid Teas are well to the fore, and among the best of them are Lady Pirrie, La Tosca, Caroline Testout, Pharisæer, Mme. Ravary, Lady Hillingdon, Liberty, La

literally smothered in bloom. Mrs. R. G. Sharman Crawford and Frau Karl Druschki or Snow Queen are the pick of the Hybrid Perpetuals, and William Allen Richardson (Noisette) is likewise flowering in profusion. In many gardens Gloire de Dijon, the sweetest of all climbing Tea Roses, is flowering as well now as in the days of June.

Pear Louise Bonne of Jersey.—This is an excellent Pear for large or small gardens, as it succeeds in so many forms of training. On a south wall, trained horizontally, as an espalier, as a cordon in the open, and, above all, as a bush, it succeeds admirably. Of vigorous yet not rampant growth, it crops freely, and with judicious thinning of the fruit handsome specimens are easily obtained. Like all Pear trees, extra attention is needed in the matter of mulching during dry weather, and if given copious supplies of sewage or liquid manure the fruit swells rapidly and colours richly. This Pear was raised about the year 1788 by M. Longueval at Avranches.—E. M.

A Beautiful Blue Greenhouse Flower. *Lisianthus russellianus*, sometimes known as *Eustoma russelliana*, is one of the most beautiful of greenhouse flowers, although a plant that is very rarely met with now. At one time grand specimens of it were exhibited, and being somewhat particular in its requirements, it was looked upon as a good test of the cultivator's ability. In these days, however, when there are so many fine subjects which can be grown with comparative ease, plants that require special management do not find sufficient favour.

A Beautiful Periwinkle.—We were very much attracted recently by a fine mass of *Vinca difformis* growing under a large Pine in Canon Ellacombe's garden at Bitton, where it has been growing for a long time. It still produces freely its beautiful blue flowers, and will continue to do so while the weather remains mild. It is a native of Western and Central Mediterranean regions, where it is found in moist and shady places, but

it is seldom met with in cultivation, due, undoubtedly, to the fact that it is not so hardy as the well-known Periwinkles. It is a valuable plant for greenhouse decoration, where it will keep up its succession of flowers during the dull months of the year. It is readily increased by means of firm woody cuttings, and requires to be cut back in the spring to keep it compact.

OCTOBER BLOOMS OF HADLEY, A DEEP CRIMSON AND SWEETLY FRAGRANT ROSE.

France, Mrs. Herbert Stevens, Lady Ashtown, Mrs. A. R. Waddell, Cherry Page and Mme. Abel Chatenay. Gustave Regis, often regarded as the best of autumn Roses, has now passed out of bloom. Of the Tea Roses, Mme. Lambard, Antoine Mari, Souvenir de Pierre Notting and General Schablikine are all flowering well; while Orleans and Jessie, both Dwarf Polyanthas, are

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

An Autumn Bee Flower: *Sedum spectabile*.

A propos the note by E. T. Ellis regarding this, on page 492, October 9, I may remark that *Sedum spectabile* has toxic effects on bees, and that many of those which go to it in search of honey become so stupefied that they cannot fly away, and succumb.—S. ARNOTT.

Club in Cabbage.—"B., Weybridge," should try Pestite, a proprietary compound manufactured by Messrs. Lang and Sons, Limited, Hounslow, W., and used largely, if not solely, by market growers. The firm will readily supply information regarding Pestite, of which there are many proofs of its wonderful efficacy as a preventive of club root in Brassicas. Personally, I am not worried by club, but I have proved the

and the soil trodden firmly about the cuttings, they will make good growth the next summer and an abundance of roots, and should be replanted the following spring. Sharp frost is often the means of loosening the soil about the cuttings, which, if not made firm again after a thaw, is often the cause of a bad "strike." A mulch of coal-ashes 2 inches thick between the rows will do much to prevent the upheaval of the cuttings.—E. M.

Japanese Windflowers.—"R. P.'s" reference on page 497 to Japanese Anemones invites me to draw your readers' attention to the variety Mont Rose, a large bed of which has been in full flower here for the last six weeks, and its beauty is so striking that it prompts one to urge its more extended planting. This variety received an award of merit from the Royal Horticultural Society in 1900, when a small basketful was shown by Messrs. Paul and Son at the old Drill Hall. It is generally described as dwarf, but this season the flower-stems have been 3 feet high, and the

contradict himself, inasmuch as he says that the correct name of any plant is that which was first given it. To this, within reason, I entirely agree. Then he goes on to say that botanists are perfectly justified in giving new names where circumstances warrant it. To this, of course, no exception can be taken, as we are continually learning; but my original note was against the persistent chopping and changing of names, in which, by the way, botanists are not always in agreement.

I was not aware of my insular prejudice, and certainly did not once dream of letting the same plant have a different botanical name in every country of Europe. I, however, do protest against acknowledging the complete reversal of the names of Ferns, which, supported by botanists of long standing and recognised all the world over, are completely upset by the conclusions to which one single individual has arrived. With regard to the name of *Matteuccia*, why not have allowed the generic name of *Onoclea* or *Struthiopteris* to remain instead of coining a new word?

Returning once more to the question of the first name given to the plant being the correct one, there are, of course, limitations to this. For instance, the delightful *Magnolia grandiflora* was, I believe, first given the specific name of *foetida*, as the flowers were received in a state of decay. There was an attempt to revive this totally inappropriate name some years ago in the United States, but, fortunately, it is not recognised in this country.

Next, anyone acquainted with our own native Hawthorn is aware that when raised from seeds a vast number of distinct kinds can be picked out, yet they are all, and rightly so, looked upon as forms of one species. In North America, on the other hand, so rich in members of the Thorn family, every individual variation from the type is regarded as a species, backed up, too, by one of the greatest authorities on the Western Continent. The words on this point by Mr. Bean in his invaluable work, "Trees and Shrubs Hardy in the British Isles," may as an appropriate conclusion be herewith quoted. The author says: "There has lately arisen a school of workers, with a strong following on the Continent and in the United States, whose aim is to subdivide species, genera and Natural Orders to the fullest extent. While much of this is, no doubt, the result of a closer study and a more critical insight than the older men practised, some of it seems to represent a desire of change for change's sake. At any rate, if adopted in its entirety, it would involve such confusion and readjustment of nomenclature as to render its acceptance by cultivators in the last degree unlikely in this country."—H. P.

Covered Chains for Roses.—As far as my experience extends, iron chains are not injurious to climbing Roses. Of course, if the chains were galvanised, the acid therein would, as in the case of galvanised wire, be liable to damage the shoots. This trouble can, however, be easily obviated by giving the iron two or three coats of good lead paint; indeed, I should be inclined to treat ordinary wrought iron chains in a similar manner before placing them in position.—T. K.

—The subject of covered chains for Roses, upon which you invite correspondence on page 480, cannot well be divorced from the general question of the use of metal in other forms. This is a question which has interested me for many years,

ANEMONE JAPONICA CRISTATA WITH SOFT PINK FLOWERS AND CRESTED FOLIAGE.

usefulness of Pestite as an insect destroyer. The powder merely requires digging in. Its cost is 9s. a hundredweight, sufficient for nearly half an acre.—T. A. W.

Propagating Shrubs.—The note on this subject, page 491, October 9, is opportune. Many desirable subjects can be increased easily with but a minimum of trouble and hardly any expense. Mention is made of Laurels; these can be rapidly increased, but I have seen many failures even with so common a shrub as this, owing to taking the wrong type of cutting—the soft top of the current season's growth, without securing with each a "heel," a piece of last year's wood, at the base of the cutting. In taking cuttings of Laurels, it is wise to slip them off by giving a sharp tug in a downward direction, which secures with each cutting a "heel" attached to the current season's shoot, some 8 inches or 10 inches long. If these are firmly inserted 4 inches apart in a trench 4 inches deep, with a base of sand or road grit,

whole bed crowded with spikes and smothered with large, semi-double pink flowers, the florets of which, being very much cut up and divided, give the flowers a light appearance.—R. W. W., Colchester.

—*A propos* the recent correspondence on Japanese Windflowers, I would like to draw attention to *Anemone japonica cristata*. This is among the most striking and useful plants cultivated in the herbaceous border, and always arrests attention. As its name implies, the foliage is quite unlike an ordinary Anemone, being beautifully crested, much resembling some of the crested *Scolopendrium* Ferns, which turn a beautiful colour during late autumn. At this season of the year it flowers profusely, the colour being a beautiful soft pink.—E. BECKETT, Aldenham House Gardens, Elstree.

Changing the Botanical Names of Plants.—In his criticism of my note on this subject, your correspondent Mr. W. R. Dykes, page 492, seems to

and about which I have from time to time received much information in gardens I have visited. All my Roses are grown on wood or against stone, but I have found some of them quite safe if attached to wires or wire netting against a wall. This is only reliable in the case of the hardiest Roses, such as the Ayrshires and kindred subjects. In some places, however, where Roses are wired against walls, it has been found necessary to see that the wires are kept painted. Chains, if left uncovered, are certainly injurious in many places, although this depends a good deal upon the climate.

Some experienced growers I have known have shown me the difference between Roses planted at the same time, but some on bare chains and others on the same covered with rope. The latter looked much healthier as a rule, and had made considerably more progress. I should certainly consider that chains covered with sections of Bamboo or wood would be much better than those left uncovered. I know some good gardeners who now eschew chains and use nothing but rope, although this requires renewal from time to time. Roses on iron arches are frequently much injured by frost, and I have in mind a certain garden where even the more free-growing Roses were so badly crippled by being grown on iron arches that the latter had to be abandoned.

There is, however, a method of forming metal Rose arches which is worth consideration, although I am only suggesting it from the experience of one of the keenest and most experienced gardeners of my acquaintance, and one of the best informed of my rosarian friends. This is to build up the

A BED OF ROSE PHARISAER.

arches with hollow iron tubes—virtually iron piping about an inch in diameter—firmly attached by means of wire. Tasteful arches may be built up in this way, and my friend assures me that he has never had his Roses injured on such arches, which he has used for a number of years. Certainly the Roses he grows on these tubular arches are always in the pink of condition, and I have seen them frequently for several years. I suppose the idea is that the current of air passing through the tubes prevents them from changing their temperature too rapidly. The point raised is an important one, especially for those who cultivate many Roses on pillars and arches, and who find the renewal of these a troublesome and often difficult matter. By the way, a good “tip” for those planting pillar Roses is to place the butt of the post in the section of a drain-pipe. If this is done, the decayed post may be removed from the pipe and a new one put in without much disturbance of the Rose and with comparative ease.—S. ARNOTT.

The “Lily of the Field.”—In the interesting account of the Sternbergias that appears in THE GARDEN of October 2, page 481, the writer repeats a statement often made, to the effect that “*S. lutea* is the supposed Lily of the Field of Scripture”; but it is agreed now, I think by all the best authorities, that the Biblical Lily of the Field is *Anemone coronaria*, which is perhaps the commonest, and at the same time the most gorgeous, flower in Palestine. Its usual hue is a bright scarlet,

surpassing the colour of the robes of “Solomon in all his glory.” It may interest some to know that the Rose of Sharon, also mentioned in the Bible, is thought to be *Crocus Gaillardoti*. The Hebrew word distinctly means a bulbous plant. These two flowers are those most sought after by pilgrims, and I have dried specimens by me as I write.—R. M., Hertford.

WILD AND CULTIVATED ROSE HIPS.

IN the reign of Richard II. Rose hips were used, with red wine, sugar, hot spices and blanched Almonds, for the making of Saracen sauce, and in the seventeenth century they were extensively used for making tarts. Compote of Rose hips is still said to be sold by the bucketful in Continental markets, but in this country their economic use has been entirely lost. To-day we treasure the brightly coloured Rose hips in autumn because they are so pleasing to the eye, but the time may again come when the Rose hips of our lanes and hedgerows may, after the removal of the seeds and hairs, be as much sought after as Blackberries. There is a variety of the wild Dog Rose that has long, arching branches with showers of bright red hips. It is known as *Rosa canina subcristata*, and it looks extremely pretty if planted in the wild garden, especially when growing near to the water's edge. *Rosa alpina lucida*, the Sweet Briar, and Janet's Pride also carry a plentiful supply of hips that look very pleasing at this time of the year. But the finest of all the Rose hips are those of *Rosa Moyesii*, a comparatively new species from the mountains of Western China, where it is found at an altitude of between 7,000 feet and 9,000 feet. The blooms, which appear in June, are of a peculiarly rich shade of red, and they are succeeded by large pear-shaped, orange red hips, some of them over 2 inches long. Other Roses worth growing for their hips are *Rosa pomifera*, with deep red gooseberry-like fruits; *R. atropurpurea*, smooth red fruits with hairy stems and purple-hued foliage; *R. rugosa alba*, with hips rather larger and brighter in colour; and *R. rubrifolia*, with deep crimson hips borne in large clusters, the foliage being a delightful grey in colour.

A FRUITING SPRAY OF ROSA MOYESII.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Rubus Veitchii.—Quite a remarkable species, having spiny growths furnished with pinnate-acuminate leaves 3 inches or so long, silvery glaucous above and whitish beneath. The flowers

for a long time. The colour is deep salmon pink, uniform throughout the flower. It should make an excellent market variety. Shown by Messrs. Stuart Low and Co., Enfield.

Cattleya Ajax Primrose Dame (Cattleya Armstrongæ × C. aurea).—Sepals and petals primrose yellow, the heavily fringed lip pale prim-

GENTIANA ORNATA, A LITTLE-KNOWN SPECIES WITH INTENSE BLUE FLOWERS.

are pink and double, and not very freely produced. As a foliage plant it is quite ornamental. From Messrs. Piper, Bayswater.

Rose Mrs. John Foster (H.T.).—This is a new seedling and was shown in capital form. Raised from Richmond and Alfred Colomb—the former the seed parent—it is similar in colour to George C. Waud, of rich vermilion hue, the flowers sweetly scented. It promises well, both as a garden and exhibition variety. Exhibited by the raiser, Mr. Elisha J. Hicks, Hurst, Berks.

Crocus pulchellus albus.—A pure white form of great beauty. The cupped blossoms have quite rounded segments, which are also of great substance. The purity of the flowers is somewhat relieved by a slight yellow base. From Messrs. Barr and Sons, Covent Garden, W.C., and Mr. G. Reuthe, Keston.

Gentiana ornata.—A very beautiful species was shown under this name, the award subject to its being verified. The handsome flowers are sessile, erect, nearly as large as *G. acaulis*, tube slightly inflated, and striated white externally. The lobes are intensely blue. Quite a dwarf plant, with acute glossy foliage on somewhat creeping stems.

Scelopendrium vulgare plumosum.—A highly decorative form with heavily crested margins and tasselled ends. It is of handsome proportions.

Aster Amellus Mrs. Perry.—A quite new shade of colour in the Italian Starworts, the flower-heads being of reddish violet. It is of capital form. These three were from Mr. Amos Perry, Enfield.

Carnation Alice.—Quite one of the best and shapeliest Perpetual-flowering Carnations seen

rose at the margin, succeeded by deep yellow, the tube of brownish crimson with gold lines. From Messrs. Armstrong and Brown, Tunbridge Wells.

CARD OF APPRECIATION.

Odontoglossum Victory (*O. crispum* The Baroness crossed with an *Odontoglossum* hybrid of unknown parentage).—A card of appreciation was given to this shapely, well-marked variety. It is characterised by huge red blotches and margined lilac white. The lip is white fringed. It is one of the most perfect forms yet seen. From Messrs. Armstrong and Brown.

The whole of the foregoing plants were before the Royal Horticultural Society on the 12th inst., when the awards were made.

NEW DAHLIAS.

Rainbow (Collarette).—The colour is rose, with yellow centre. Shown by Mr. J. B. Jarrett, Anerley Road, S.E.

Anna Louise (Collarette).—Of ruby red colouring and very good form. From Mr. J. B. Riding, Chingford, Essex.

Leviathan (Decorative).—A distinct and good form, in which orange salmon and terra-cotta mingle, the dominant colour being orange. From Messrs. J. Stredwick and Sons, St. Leonards.

These Dahlias, having been adjudicated upon by a joint committee of the Royal Horticultural Society and the National Dahlia Society, carry the award of merit of the former and first-class certificate of the latter.

THE PREPARATION OF BEDS FOR ROSES.

EACH year, as the cultivation of Roses becomes better understood, more importance is being attached to the preparation of the soil in which they are to be planted. All good growers now realise that it is well-nigh im-

possible, except under natural conditions that are particularly favourable, to grow Roses of good quality unless the soil has been previously well and deeply tilled, drained and manured. Unfortunately, many would-be Rose-growers have little, if any, choice of site. They must, perforce, make the best of existing circumstances; and as November is the principal month of the year for planting, a few hints concerning the preparation of the beds may be useful.

For all practical purposes, soils may be roughly divided into two sections, viz., those in which clay predominates, and known in garden parlance as heavy soils, and those in which we find a preponderance of sand, chalk or flints, and known as light soils. In a few instances there may be gardens the soil of which cannot, even by a stretch of imagination, be classed in either of the above categories, but such are seldom met with. Generally speaking, heavy soil is the best for Roses, unctuous clay, which is difficult to till, but which improves greatly by working, suiting all the strong-growing kinds to perfection. Where this naturally abounds, it is practically certain that artificial drainage of some kind will be necessary before the successful cultivation of Roses can be undertaken. Undoubtedly the ideal plan under such circumstances is to lay pipe drains about 2 feet below the surface, and so drain the whole area. Where an outlet at a sufficiently low level is obtainable, this is not a very difficult task, and has the merit of being comparatively permanent.

On the other hand, the soil, though wet, may not be sufficiently so to demand pipe drains, and here it is that deep tilling and judicious manuring are brought into play. The soil ought to be trenched to a depth of not less than 2½ feet, keeping the bottom soil in its original stratum, but mixing with it a liberal supply of rather long, partially decayed stable manure, or that from a farmyard in which horses only have been kept. This manure has a lightening effect on the subsoil, and may come to within 9 inches or a foot of the surface. Not only will it provide food for the Roses, but it will very largely bring about that free drainage so much desired. With the top 9 inches or 12 inches mix quarter-inch crushed bones, wood-ashes, a little old mortar, or scrapings from a country road not frequented by motors. This will render it more friable and in better condition for planting. Beds formed in such soil as this are best raised 9 inches above the surrounding level. Heavy soils are best adapted for Roses budded on seedling Briar stocks, though other stocks do very well if thorough drainage is secured.

Unlike heavy soils, those which come under our second heading call for a large amount of ingenuity and skill if we would have Roses of the finest quality. Here, again, deep tilling must be adopted, not for the purpose of drainage, but, paradoxical as it may seem, to conserve moisture. In heavy soils it is water that descends from the surface that we wish to get rid of; in light soils it is the moisture that rises from the bowels of

the earth, by capillary attraction, that we wish to conserve, deep cultivation in both instances affecting these ends. But it is not only the breaking up of the soil where it is poor and light that must be attended to. Rich soil of a retentive texture must be added to the top spit, and manure put with that below. Here stable or horse manure would be of little use; that from the pigsties or cowsheds must be used in abundance, and it ought to be as short and decayed as possible. It will afford a cool and nourishing rooting medium for our Roses in the hot and trying days of summer. Where flints or rocks abound, these must, as far as possible, be taken out and replaced with the best soil obtainable. Where the subsoil, a foot or rather more below the surface, is almost pure sand, nothing can be done except to remove it to a depth of 2½ feet and replace it with good soil. This is, of course, a very costly process, and one that could not be carried out on a large scale; but if Roses are to be grown, it would be found more economical, and far more satisfactory, than planting bushes in soil that is entirely unsuitable, and in which they would be foredoomed to a lingering and unhappy existence. Beds in light soils are best sunk 6 inches or 9 inches below the ordinary level. Deep cultivation, with manuring suitable for the kind of soil that is being dealt with, are the synonyms to the initial and most important stage of Rose-growing, and it is only by the due observance of these that Roses of even moderately good quality can be obtained.

Planting, no matter whether the soil is heavy or light, ought not to be done until at least a fortnight after the beds have been trenched, so as to allow the soil time to settle down. In very stiff clay soil it is best to prepare the beds in autumn, leave the surface as rough as possible, and postpone the planting until the following March. The frosts and winds of winter have a mellowing effect on the soil and render it in much better condition for planting.

PERNETIANA ROSES DURING 1915.

THESE Roses have maintained their reputation in the usual glorious colours. During early summer and again in St. Martin's summer they are clothed in gorgeous array, vying with each other which is queen. My Pernetianas are in beds of thirty-six plants, and give a fair idea of the beauty of this new race.

Beauté de Lyon has bloomed beyond its reputation, both early and late. Rayon d'Or has quite left behind the weedy growth of its early days in England, and throws up thick shoots, with shimmering foliage crowned with large golden yellow blooms. Our old friend the Lyon Rose is as good as ever, looking on complacently while her children almost make her take a back seat. One of my successes has been Mme. Edouard Herriot, the *Daily Mail* Rose. From May until now (September 18) it has been one glorious mass of bloom, and promises to continue until King Frost sends it to rest. No garden can be complete without this wonderful Rose. Soleil d'Or, Soleil d'Angers, Rodophile Graveraux, Viscountess Enfield and Mme. Ruau have all bloomed well. So, too, have Johannesfeuer and Louis Barbier. The stately Juliet—pegged down, please—has been perfect.

Cissie Easlea has been another "great" Rose this year. Nothing small about this. All the shoots are thick with red thorns and shimmering foliage. The blooms are creamy yellow, tinged with fawn and faint carmine, after the style of growth of the charming Louise C. Breslau. Lady Mary Ward, Old Gold, Mrs. F. W. Vanderbilt, Arthur R. Goodwin and F. J. Barry seemed to have raced Mme. John Crouch and Marie Adelaide Grande Duchesse de Luxembourg, each of them full of beauty in its own particular way. Iona Herdman has never been out of bloom. It is a vivid Rayon d'Or yellow, not too full; long, delightful yellow buds, and beautiful in all stages. You must have

this. Mrs. George Beckwith is going to be a surprise to everyone.

Many doubtful rumours have been heard about Constance, but everyone should grow it. It is a great advance on Rayon d'Or. The long buds are streaked with crimson; it has a branching habit of growth, the usual red thorns and shimmering foliage. Now for the blooms. Several of mine before me at the moment are 5½ inches across. They are perfect in all stages of the bloom, even after the full perfection of shape has passed away. Plant Constance; you will like this, and it is constantly in bloom. Willowmere, Mrs. Charles E. Pearson and Autumn Tints must not be forgotten; they, too, have contributed their share of colour to the whole. The Rose year of 1915 has proved Mme. Edouard Herriot and Constance. Whatever other Roses you omit from your usual order, double and treble both of these.

I must not forget to add that a bed containing thirty-six plants of Persian Yellow was one of the greatest treats of the year; but as this variety only blooms once, it should be planted where a bed of it can act as a background of green to other varieties, or it will spoil the colour scheme of a Rose garden. Persian Yellow arrived in England early in the reign of Queen Victoria, and its manners and colour won the admiration of the rosarians of that day. Soleil d'Or and later on the Lyon Rose, members of Persian Yellow's family, were raised by M. Pernet-Ducher, and they proved to be the forerunners of the Pernetiana Roses.

EVELYN E. FARMER.

THE MUSK ROSE OR ROSA MOSCHATA, THE WILD BRIAR OF THE HIMALAYAS.

ROSES IN YORKSHIRE.

THE class of Roses known as "decorative" has received a great deal of attention during late years. The strides made in this direction are immense, and one has noticed that in a show of any size they are always well represented and universally admired. In my opinion, one of the finest and most delightful additions to the ranks of the "decorative" Rose is

Old Gold, truly a lovely and distinctive variety. I only planted this last autumn, but it has fulfilled all that the raisers claim for it. It is semi-double, a picture in the bud stage, old gold tinged with scarlet, paling off somewhat as the flower expands. The blooms are borne on strong, stiff stems; the foliage is very free from mildew; while it has a fine branching habit of growth. No one should fail to find room for it. It is a worthy companion to Irish Fireflame. Another "decorative" or garden Rose that must be mentioned here is

Hilda Richardson. Although not so effective as Old Gold in shape and style of bloom, yet its colour is very charming—a rosy lilac on white ground. It has a vigorous branching habit and is extremely free flowering, right on into the autumn; but to me its great charm is its delicious and powerful scent, which alone makes it worth growing, even if it suffered from every pest and defect known to rosarians. One cannot imagine a more refreshing odour than that from a bowl of this variety on the table, unless it be that from a Rose as yet but little known, but destined

surely to become a most popular variety. I refer, of course, to

Mrs. George Norwood, which, in addition to its soft pale pink (even more delicate in colour than Mrs. R. G. Sharman Crawford), carries with it a fascinating perfume that commends it to everybody. It must have a future for shape and perfume alone. This is another variety that one gives a repeat order for, even in war-time.

Louise Catherine Breslau is a comparatively new Rose (1912) that I much like. It belongs, of course, to the Pernetiana class, and is at home in the bed containing Lyon, its coppery orange and yellow tones according well with the better-known Rose. The buds are very choice—tones of coral red and chrome yellow, and the blooms last a very long time either when over-blown or in water. Its fault, if any, is its habit of growth, which is rather too horizontal. One of my discoveries this season has been

Elise Robichon, a veritable gem among climbers. Its colour is pinky buff in the bud state, opening to very pale blush, and the plant is continually in bloom. Its foliage is bold and glossy, and of the character of that of Alberic Barbier.

The one Rose that has disappointed me is

Earl of Warwick, a really beautiful Rose when well grown, but it does not seem to excel in this climate, and it is one to do without. Now that the planting season is approaching, we are going to experiment again, and hope the winds of Yorkshire will be kind to such varieties as H. V. Machin, Florence Forrester, Lady Mary Ward, Iona Herdman and others whose fair presence we impatiently await in our gardens.

Roundhay.

E. WATERS.

A BEAUTIFUL PILLAR ROSE.

For pillars or pergolas Ethel is one of the most delightful of all varieties. It is a seedling from Dorothy Perkins, raised three years ago by Mr. A. Turner, The Royal Nurseries, Slough. Its semi-double flowers, clear flesh pink in colour, are borne in large trusses in great profusion. Its vigorous habit of growth, and beautiful light green foliage bring to mind Dean Hole's famous tribute: "Pillar Roses, some rising here and there, like the proud standards of victorious troops; some meeting in graceful conjunction like our forefathers and foremothers in the stately minuet—bowing themselves like tall and subtle cavaliers into arches of courtesy." For table decoration it is specially to be recommended, for the flowers light up admirably under artificial light. Few Roses are so well adapted for making weeping

MR. AND MRS. MAWLEY AT HOME IN THEIR ROSE GARDEN.

COLOURED PLATE.

PLATE 1504.

THE SINGLE ROSE PRINCESS MARY.

SINGLE Roses invariably possess a charm peculiar to themselves. The wild Roses of our hedgerows, which were so glorious in the month of June, are now radiant with their arching sprays of scarlet hips, and a source of admiration to naturalist and rosarian alike. In the new seedling Rose Princess Mary we have a gem of the first water that stands unrivalled in its rich deep crimson colour. The flowers are large, with bright golden anthers that stand out in gorgeous contrast to the lovely velvety sheen on the upper side of the petals. It is indeed a flower of a most refined finish, and, beyond all, it possesses in a high degree the precious gift of fragrance. Moreover, it flowers over a very long season, for it is almost as gay with flowers now as it was in the days of June. In growth it is fairly compact and upright. It is a capital bedding Rose, and also makes a good standard. It may come as a surprise to many to learn that it is the result of a cross between Richmond and J. B. Clark, both crimson Hybrid Teas, it is true, but both have full blooms and bear no resemblance to the five-petalled Princess Mary. Like most single Roses, the colour of the flowers is better on the growing plants than it is in the cut state. The foliage is dark green, and we believe it to be practically mildew-proof, which should add considerably to its value. Our coloured plate is prepared from blooms kindly supplied by the raiser, Mr. Elisha J. Hicks of Hurst, Berks, who is to be heartily congratulated on his production.

PILLARS OF THE NEW ROSE ETHEL.

ROSES ON WALLS.

By EDWARD MAWLEY, V.M.H., PRESIDENT OF
THE NATIONAL ROSE SOCIETY.

HERE are few ways in which climbing Roses can be set off to better advantage than when planted against a wall, and lucky are those Rose-lovers who have such walls on which to train them. When I came to Berkhamsted thirty years ago, I found a high wall at the top of the kitchen garden, facing south. On this wall were trained a few old fruit trees, and I must

itself justice. About eight years ago there was sent me from Australia a plant of Climbing White Maman Cochet, which I was delighted to have. I planted it among the Teas in the upper and warmer part of the Rose garden, and it was given every attention. But although it made excellent growth and became quite a big bush, it never flowered. Last autumn the idea occurred to me to transfer it to the south wall in the kitchen garden I have just mentioned, and, greatly to my surprise and delight, it has this year flowered splendidly.

But to turn now to the real object of this article, which is to try to give some idea as to the best

the year. Besides being continuous flowering, a good climbing Rose should be sufficiently hardy and as little subject to mildew as possible. Then there are certain kinds which will thrive in the broiling sun better than others, and others, again, that will even present a fairly gay appearance on a north wall.

To take the latter position first; that is to say, the best varieties to plant against a wall facing north. These are few in number. First, I should place the old and tried friend which I have just described, Bennett's Seedling. This, as I have shown, is by no means continuous flowering; but if planted in conjunction with Climbing Aimée

A WEALTH OF BLOSSOM IN A HIGH HEDGE OF CLIMBING WICHURIANA ROSES.

needs regard it as the proper thing to do and accordingly added to this collection, with the result that I have had reason to regret doing so ever since, for the yield of fruit has been very precarious, and at no time worth the splendid wall space devoted to it. I, however, did manage to work in two Roses, a Gloire de Dijon and a Bouquet d'Or, which it has been a pleasure to look upon ever since. This year, notwithstanding their age, they have flowered remarkably well and continuously.

Then, again, it is wonderful how a warm wall will often influence a shy-blooming variety to do

Roses to grow on walls of different aspects, whether they be house walls or garden walls of different heights. In the first place, a decided preference should be given to those varieties which are continuous flowering. To give an instance from my own garden. I have a Bennett's Seedling growing on my house, which, when in flower, eclipses every other Rose I have, for when fully out its fragrant trusses form one unbroken sheet of pure white from the roof to the ground and from one end of the front to the other. But, alas! that splendid sheet of white Roses lasts but a few weeks, and then its glory is over for

Vibert, the latter would start flowering after my friend had finished his burst of bloom for the year, care being taken that they are kept fairly well apart. Gloire de Dijon, which is one of the most continuous-flowering Roses we have, might also be tried. It ought to do well, considering that during the last sixty years it has made its appearance on more walls in the United Kingdom of all aspects than any other Rose whatever.

For a wall facing south I would suggest Mme. Alfred Carrière (blush white), to my mind the most beautiful and reliable of all the so-called continuous-flowering Roses. Rêve d'Or (buff

yellow) might be inserted to represent the yellows. At the present time a plant of this variety is flowering most freely on the south side of a parish room, where I planted it many years ago. On a dwarfed wall, Lady Waterlow, with its delightful pale salmon blush flowers, tipped pink, would form a charming object, and in such a position its autumn-flowering proclivities would be encouraged. Here, too, might be planted with advantage Climbing White Maman Cochet, before mentioned; also Climbing Mrs. W. J. Grant (deep rosy pink), which also is often at its best in the autumn when many other autumn-flowering climbers are over.

For an east wall it would be well to choose Roses whose foliage can withstand the hot sun and cutting easterly winds so often prevailing in the spring. For this purpose one could not do better than start with that hardy and early, fragrant-flowering rugosa Conrad F. Meyer, with its large, silvery rose tinted blooms. Here, too, should come in again our old friend Gloire de Dijon, or, perhaps better still, Bouquet d'Or. Ards Rover (dark crimson) is often recommended for an east wall, but I myself should be afraid that in such a position it would be more than usual subject to mildew. For a pink variety Climbing Caroline Testout might advantageously be inserted.

For clothing a west wall, Climbing Aimée Vibert would be most appropriate, as it bears its trusses of white flowers so late in the season. William Allen Richardson, a well-known and favourite Noisette, might also be used on a west wall, for it is evidently the rapid changes that take place in the spring and early summer which cause it in other situations to be often so unreliable in its first flowering. Reine Olga de Wurtemberg, with its fine foliage and bright crimson flowers, should also clothe a west wall to advantage.

THE ROSE GARDEN OF EUROPE.

ONE summer's evening a party of three—two friends from Ireland and myself—were seated in the courtyard of an orphanage in Sofia. We were drinking Turkish coffee and discussing the merits or otherwise of Bulgarian sour milk and its relationship, if any, with the bacillus of long life. One of my Irish friends, expressing himself very strongly on the subject, said that he preferred to die young rather than to eat or drink sour milk. At this juncture a carriage drove into the courtyard and pulled up before the entrance to the orphanage. To our surprise it came from the Royal Palace. A messenger alighted and in perfect English told us that King Ferdinand, having heard of the arrival of three plant collectors in Sofia, would like to see us on the morrow. And so it came about that next day, after passing through some of the squalid streets of Sofia, we found ourselves in audience with the King at the Royal Palace. That he is a clever, interesting and cultured man, no one will gainsay. He showed great interest in our projected tour, and gave us valuable assistance. But he is so unlike his people. The country is poor, and signs of poverty are seen on all sides. The King lives in luxury in palatial buildings with all the pomp and extravagance of Court life. He loves an ostentatious show of wealth and lavish decorations. What a contrast to his neighbour, King Peter of Servia—the peasant King as he is often called! One does not need to be in Bulgaria long to realise that King Ferdinand is far from popular with his subjects.

He is, in fact, an unnatural King, holding his position by genius of intrigue, of which he is a master hand.

We left the palace in the afternoon and proceeded on our way to the Rhodope Mountains. Darkness was setting in when we halted outside a peasant's hut about half way up Mount Vitosch. The peasant was near by, tending sheep and goats on the mountain pastures, and his spouse, Baba, who, by the way, was considerably over a hundred years old, was bringing water and fuel to the hut. We approached the shepherd, who was clad in sheepskins and wore sandals and a bearskin cap, and asked him if we might spend the night in his hut or in one of his cattle shelters. On learning that we were English and Irish, he took us to his hut and made us welcome. Nothing could have been more crude and primitive than this dilapidated dwelling, and yet it was the typical home of the Bulgarian peasant. The walls were of mud plaster, and the thatched roof had a sieve-like appearance. Our faces lighted up as we observed that the only attempt at decoration was a portrait of Gladstone cut from a newspaper and pasted on the wall. The name of Gladstone is honoured above all others by the Bulgarian peasants and they talk fondly of him.

A Valley of Fragrant Roses.—We journeyed eastward to Stara Zagora, and thence to Kazanlik. Never shall I forget the scene one early morning in June, when from a hilltop we looked across a wide and fertile valley filled with fragrant Roses. Bulgarian women, young and old—some of the younger ones wearing Roses in their hair—were busy gathering Roses and taking their full baskets to the distillery near by, where, after a long and tedious process, attar of roses is prepared. The opened and half-opened

buds are gathered when the early morning dew is on them. It is only on cloudy days that picking is continued after ten o'clock. Roses gathered when the sun is hot on them have a comparatively feeble odour, and yield much less attar. It is interesting to observe that the Rose grown is *Rosa damascena*, a variety not known in an uncultivated condition. The hedges of the plantations are usually defined by a white form of the Damask Rose, and the flowers are usually mixed indiscriminately with those of the red Rose when harvesting takes place. The flowers are picked with their sepals on; these are not separated, the whole flower being distilled. It takes about 100,000 Roses to yield an ounce of attar. The Rose bushes are planted close together, forming compact hedges about 6 feet in height extending as far as the eye could see.

Our party of three left this gorgeous Eastern scene hopeful that we might return to it in the June of another year. A strange turn of the wheel has brought back the writer of these notes from the trenches of Flanders to the scene of his former labours; while, alas! one of the party, as announced in our last issue, has found an honoured grave in the Dardanelles.

C. Q.

GATHERING ROSES NEAR KAZANLIK, BULGARIA.

ROSE HEDGES.

HOW TO MAKE AND MAINTAIN THEM.

A MORE beautiful feature can hardly be imagined than a good hedge of Roses when in full bloom, yet I am often surprised, not to say grieved, to find such unprofitable plants as Privet, Box or Yew occupying fine positions that might with advantage be planted with Roses. It is, perhaps, hardly possible to keep a Rose hedge quite so neat and trim as the shrubs mentioned can be kept; but the Rose is one of the most adaptable of plants, and if a judicious selection of varieties is made, a hedge of almost any desired form or size can be created.

For Low Hedges the different varieties of Polyantha and China Roses are very useful. Each of these classes blooms most freely and perpetually, and would be a pretty sight right through the summer and autumn. The common China, especially, is an ideal hedge-maker, growing sufficiently strong to form a compact screen 4 feet or 5 feet in height. Some of the moderate-growing species might also be used with advantage, such as Rosa Hugonis, R. Ecæ, and Austrian Yellow or its lovely variety Austrian Copper, all of which give beautiful single yellow blooms in abundance in the early summer.

A Medium Hedge may be obtained by planting such dwarf Roses as Hugh Dickson (crimson), Caroline Testout (silver pink), Snow Queen (white), La Tosca (salmon pink), and Mme. Abel Chatenay (salmon). Grüss an Teplitz is a most effective hedge-maker, and I know of a fine specimen in a large public Rose garden which is a grand sight throughout the summer and autumn. For freedom of flowers there is nothing in the Perpetual classes to equal it. The Moss Roses and the Rugosas rubra and alba are also valuable, especially the last two, which, after giving a fine display of large red or white single flowers, are covered with beautiful scarlet fruit in the autumn.

Tall Hedges.—For a fairly tall hedge the common Sweet Briar is quite suitable if clipped occasionally. The scent from such a hedge is very powerful, especially after a shower and in the evening. I have heard it said that a real protective hedge cannot be formed with Roses to be as effectual as Whitethorn, but I doubt whether any person or animal would attempt to break through a hedge of such varieties as Flora (Ayrshire), Una (Hybrid Briar), Aglaia (Multi-flora), Mrs. O. G. Orpen (Hybrid China), Bennett's Seedling (Ayrshire) or Madeline Filot (Rugosa). These varieties are armed with most cruel hooked spines, and would quickly make an impenetrable hedge. On the other hand, it might be objected that a Rose hedge planted near a walk might be troublesome and tear the clothes of passers-by; but even in this case suitable varieties can be planted, such as Morletti (Boursault) and Zephyrine Drouhin, both of which are thornless, the latter being also one of the sweetest Roses in cultivation, both in colour and scent.

Supports for the taller hedges must be provided, and substantial wood posts connected by wires are best. Plants should be 15 inches to 18 inches apart in the case of the dwarf growers; 2 feet for such as Hugh Dickson, Grüss an Teplitz, &c.; and 3 feet in the case of the Wichuraianas. If a thick hedge is desired, a double row might be

planted. All the varieties should be cut back to about two feet the first year to encourage bottom growth, excepting the Wichuraianas, which may be left almost full length. Afterwards, all the pruning needful is to take out the old useless wood each spring, in order to encourage fresh growth and to keep up a healthy appearance. Nor must the matter of feeding be overlooked, liquid manure and Wakeley's Hop Manure being most desirable. If possible, own-root plants should be used, especially in the case of the climbers proper, as the suckers thrown up by budded plants are often a great nuisance. W. A. E.

FRAGRANT ROSES.

BY THE REV. DAVID R. WILLIAMSON.

I HAVE occasionally made the incidental observation, when writing upon this fascinating subject, that a Rose without the essential attribute or element of fragrance was like a beautiful woman devoid of sweetness of nature, or what is generally termed amiability. When I was recently asked by a young lady of uniquely charming physical aspect to compose some verses for her autograph book, I sent her the following improvised lines:

"I sing not, Lady, that thy charms are rare,
For outward grace alone finds not the heart;
But that thy nature, like some radiant air,
Born of the Dawn, bids inward clouds depart."

But when a Rose, like this highly endowed yet quite unaffected maiden, has both characteristics, it is as near an approximation to absolute perfection as imagination can conceive. Varieties of the Baroness Rothschild family, which is now an exceedingly comprehensive one, such, for example, as Merveille de Lyon, which made such a sensation when it appeared, and the more recent and much more impressive Snow Queen, though assuredly grandly effective "introductions," are far less valuable from an odorous point of view than the glorious old Devoniensis (which very few modern Tea Roses, however radiant in their colouring, completely eclipse) or the still widely cultivated and fondly cherished Gloire de Dijon. For at least ten or twelve years I had an unusually fine specimen of Devoniensis growing in front of my study window in Kirkmaiden Manse, which, chiefly by reason of what I would venture to term its amiability of aspect and its gentle yet subtly diffusive fragrance, "like odours rapt from remote Paradise" (as Tennyson once sang in his now unpublished "Timbuctoo"), was, during that comparatively long period of assiduous Rose

THE NEW SEEDLING ROSE FLAME OF FIRE. (See page 525.)

culture, my predominating attraction. For many years after the death of this great favourite I was chiefly fascinated by the odorous charms of the still almost incomparable La France; and now, for similar reasons, I am almost equally attracted, in the terraced garden of Kirk House here (where I am only a quarter of a mile from the Manse), by one of its grandest derivatives, Edgar M. Burnett, eminent among Mr. S. McGredy's most recent—and assuredly one of his finest—creations. Mr. Arthur William Paul's floriferous Majestic, which was awarded the gold medal of the National Rose Society, and sometimes reminds me of my English Rose namesake, also raised at Waltham Cross, is a richly odorous acquisition.

The great majority of the China, Austrian and Penzance Hybrid Roses are, like the old pink Provence (parent of the beautiful Moss varieties), extremely fragrant, many of them in foliage not less than in flower. Perhaps of all Hybrid Teas at present in cultivation, the most odourously attractive are La France and General Macarthur, the latter of which was first strongly recommended and subsequently sent to me by Mr. Walter Easlea, a highly accomplished English hybridist and rosarian. Several of the finest of recently originated Irish Roses, natives of the world-renowned nurseries of Newtownards and Belmont, are endowed with an exceptionally refined gift of fragrance, which has descended to them, from Maréchal Niel. Supreme among these are such almost peerless beauties as Miss Alice de Rothschild, Mrs. Wemyss Quin and Mrs. Archie Gray,

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Figs.—The second crop of Figs will continue to ripen so long as the atmospheric conditions are suitable. Maintain a little warmth in the pipes, and keep the ventilators open both top and bottom. This will not only encourage the fruits to ripen, but will also help to ripen the wood, which is of great importance for the success of next season's crop.

Fig Trees in Pots.—If it is intended to place the early trees into the forcing-house early in November, those which have their wood perfectly matured must be selected. These must be pruned and cleaned; and should there be any doubt about the wood being matured, keep them out in the open for a week or two longer. The pruning consists chiefly in thinning out the shoots where they are too thick and removing useless spray. Great care is necessary in the early forcing of Figs till the growth and roots are active. For the first few weeks no artificial heat is necessary.

Late Grapes.—There should be no Grapes unfinished by this date, as the weather this season has been exceptionally favourable. It may still be necessary to water the roots where the borders are inside. This operation should be done on a fine morning; and to prevent moisture from rising to the bunches, thin layers of clean straw should be scattered over the border after watering. Go over the bunches once a week to remove bad berries; and where mealy bug is present, care must be taken that these insects do not enter the bunches.

Plants Under Glass.

Roman Hyacinths.—If these were potted as advised in a previous calendar, they should now be ready to be taken from the ash-bed. Place them in a cold frame to expose them to the light. They may be taken from the frame to force in batches as desired.

Paper-White Narcissi.—These also should be ready to be moved from the ashes into cold frames. Before placing Narcissi into heat, it is essential that the pots are full of roots. Do not place them in a high temperature, or many of the bulbs will fail to flower.

Primula sinensis.—The earliest plants will now be throwing up their flowers. They will need plenty of stimulants, as the pots will now be full of roots. Soot-water given once a week will considerably improve the colour of the flowers. *Primula obconica* is a most useful plant for the conservatory during the autumn and winter months. If given liberal treatment in regard to watering and feeding, they will continue to flower during the greater part of the winter.

Poinsettias.—These plants will now be developing their bracts, and it will be wise now to somewhat lower the temperature of the house. At this period a circulation of air, coupled with a little warmth in the hot-water pipes, will create the desired atmosphere. A temperature of 50° or 55° will be quite enough unless the outside conditions are unusually warm. These plants will not need so much moisture at the roots, but they must not suffer in this respect.

Pelargoniums.—To keep these flowering as long as possible, the house must be well ventilated, and during damp weather a little heat must be turned on. The plants will require plenty of water, but they must not be overdone in this respect, or growth will be soft, which is not conducive to good flowering.

The Flower Garden.

Replanting Herbaceous Borders.—When the spring bedding is finished, attention should be given to the overhauling of hardy flower borders. Herbaceous borders need replanting every two or three years, but it is possible that many will have to be neglected in this matter through shortage of labour, from which every garden is more or less suffering at present. If time will not allow of the plants being taken up and replanted, the clumps should be gone over and reduced where necessary, afterwards carefully forking in some well-rotted manure between the plants. Before cutting down the plants, see that they are all correctly labelled.

Roses.—I have never seen the autumn Roses so good as they have been this season. *Mme. Abel Chatenay*, *Arthur R. Goodwin*, *General Macarthur*, *Rayon d'Or*, *Lady Hillingdon*, *Mme. Ravary* and *Mme. Jules Gravereaux* have been splendid. With favourable weather the plants promise to supply good flowers for some time to come. Keep the beds clean, and hoe between the plants when the soil is in suitable condition.

The Hardy Fruit Garden.

Winter Dressings.—A systematic spraying of fruit trees during the winter and spring months is now generally recognised by all fruit-growers. The first dressing should be given in the autumn, when the insects are going to their winter quarters to lay their eggs. Grease-proof bands are excellent traps if placed in position early enough to trap the insects when they are ascending the trees. These are inexpensive and may be procured ready for use.

The Kitchen Garden.

Cauliflowers.—These must be gone over regularly, with the object of protecting the heads from frost. Those that are fit for use may be pulled up and laid in a cool shed, where they will keep fresh for several days. Others may be protected by their own leaves. Later on, when severe frost is expected, those which have just commenced to turn in may be carefully lifted with a good ball of roots and placed closely together in cold frames.

French Beans.—Another sowing of these may be made in 7-inch pots and placed in a warm house. When the plants are through the soil, place them near to the glass. The plants which are fruiting in cold frames must be given plenty of air, or they will damp.

Rhubarb.—It is time now to prepare roots for forcing. When the foliage has died down, lift the roots and lay them in a shed for a few days before placing them in the forcing-pit.

Tarragon.—A supply of this useful herb may be kept up by placing roots in a warm house every three or four weeks. Plant the roots thickly in cutting boxes and thoroughly soak them with water.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Flower Garden.

Planting Roses.—Where it is possible to do so, this work should be commenced now, and, if possible, completed before the severe winter weather arrives. As Roses continue to form roots through the winter, during open weather, the advantage to be gained by early planting will be readily seen. In most gardens dwarf Hybrid Tea Roses become exhausted after three or four years. If the plants are carefully lifted and heeled in temporarily while the beds or borders are being trenched and enriched with manure and fresh loam, if available, they can be replanted, and any very worn-out, weak plants replaced by young stock. When this is completed, they should be protected from severe frost by a covering of straw or Bracken.

Bulbs.—Any of the summer-flowering bulbs, such as *Gladiolus* and *Hyacinthus candicans*, which may yet be remaining in the ground, should be lifted before there is any danger of them being injured by frost. It is best to let the stems thoroughly ripen before severing them from the bulbs. This will take place in a few weeks' if they are hung up in a well-ventilated shed.

Plants Under Glass.

Nerines.—These plants are now pushing up their flower-spikes, and should be given a little top-dressing if there is sufficient room for applying it. They should not be repotted more frequently than once every third or fourth year. As growth advances, some help may be given with liquid manure.

Chrysanthemums.—The bulk of the late-flowering varieties now being indoors, there is danger of overcrowding the plants. Not only is disease spread and encouraged by growing the

plants too closely together, but weaker blooms and stems result. The growths at the base of the plants ought not to be removed after this date, as they will be available for cuttings in a few weeks. Great care must be taken when watering the plants not to splash any unnecessary water on the floor or stages if there are any flowers open, as this causes the petals to damp. In the case of single-stemmed plants, laterals must still be watched for closely, as they are sometimes apt to make a quick growth quite unobserved beneath the large foliage.

Tree Carnations.—Plants which were potted in 6-inch and 7-inch pots in July are now well established, and call for more frequent tying of the flowering shoots as they develop. A little weak soot-water, also Clay's Fertilizer, given in the water helps to encourage a free and firm growth. Keep a little heat in the pipes to help to dispel any abundance of moisture in the houses, but allow it also to escape naturally by the use of both the top and bottom ventilators.

The Hardy Fruit Garden.

Strawberries.—If the runners have been regularly cut from the plants, and weeds well kept down, there is not much need for forking between the rows at this season; but where weeds abound, there is generally a multitude of small seedlings, which give a Strawberry bed an untidy appearance. Where this is so, a light forking over should be given, but not deep enough to endanger any of the roots.

Gathering Fruit.—Late varieties of Apples should be pulled as they become ripe. Some of the Greenings are only ready after this date. Premature gathering means shrivelled fruit with loss of flavour.

Fruit Under Glass.

Melons.—Where there is a large batch of Melons maturing fruit, slightly different conditions are necessary from the usual treatment given to summer crops. With sunshine not being so plentiful, more pipe heat is essential. A high temperature should rule night and day until the fruit is quite ripe. When there are a few hours of sunshine, opportunity should be taken to open the top ventilators slightly, just sufficient to allow the moisture to escape and keep the atmosphere wholesome. Watering of the plants should cease altogether as soon as there are signs of ripening.

Peaches and Nectarines should be looked over frequently to see if the borders require water. Copious waterings should be given until the leaves fall. Neglect in this direction would mean bud-dropping and failure of next season's crop.

The Kitchen Garden.

Tomatoes.—Plants which are bearing should be given help by top-dressing, also stimulants in the water. This, however, should only be done with discretion, as sunshine being less plentiful and the days shorter, the plants are not able to assimilate such quantities nor so quickly as they would do during the summer or autumn. Ventilation should be given freely during fine weather, avoiding too close an atmosphere, which would have a bad effect on the plants.

Celery.—Take advantage of every favourable opportunity to get the final earthing completed. Even the latest batch of all should not be too long deferred, or there will be a danger of getting it destroyed by frost.

Celeriac.—Where this vegetable is grown, it should now be lifted and stored much in the same way as one proceeds with Carrots and other root crops.

Digging and Manuring.—Where it is possible, proceed with this work. It is a great advantage to many crops if it can be done early, as then the soil is exposed to all the beneficial influences of the winter weather. For such crops as Onions and Peas it is of special advantage.

Seed Potatoes which are now ready for storing for the winter should be looked over and any diseased tubers removed. The best method is to keep them spread out in trays or shallow boxes away from frost, but cool and well ventilated.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

SOME GOOD NEW ROSES.

AT the Autumn Show of the National Rose Society, held recently, there were some very good novelties exhibited, some of which had previously received awards, so were not included in the list published in our issue of September 25. Several of these are not yet in commerce, but it will be well to note them for further guidance, as unquestionably they will be wanted. The names in parentheses indicate the raisers.

Climbing Mme. Abel Chatenay.—A very vigorous sport of this popular favourite, making, on maiden plants as shown, growths 6 feet to 7 feet long in a season, and no doubt under glass even of greater length than this. This fine sport will rank in usefulness equal to Climbing Mélanie Soupert, Climbing Sunburst, Climbing Mrs. Grant, &c., and cannot fail to be largely planted when it is distributed. (Walter Easlea.)

C. K. Douglas.—A very large petalled Hybrid Tea Rose of glorious scarlet crimson colour, reminding one of Brilliant, only apparently fuller and superior. (Hugh Dickson, Limited.)

H. P. Pinkerton.—A vigorous Hybrid Tea Rose with nice-shaped flowers of a coppery pink shading. (Hugh Dickson, Limited.)

Queen Alexandra (Perpetual Climber).—The flowers are something like Una, only a little smaller, with the edges of the petals on the reverse side a blush pink, giving a very beautiful impression in the mass. (Rev. Joseph H. Pemberton.)

Galatea (Perpetual Climber).—Like a double form of Moonlight. There does not appear to be any room for a Rose of this description, and those who will plant it will be very limited in number. Roses of this class must be perfectly distinct and attractive to command public attention, and we shall soon be overburdened with them unless discretion is employed by raisers. (Rev. Joseph H. Pemberton.)

Lady P. Moore (H.T.).—A very double and large Rose of soft blush pink shading. In form it resembles Mrs. Cornwallis West. Should be a good stayer to the exhibitor.

Cheerful (H.T.).—A lovely bit of colour, at first sight recalling a good-coloured Juliet without the old gold suffusion on back of petals. It is a large flower, as big as Caroline Testout, so should prove a splendid decorative sort. (S. McGredy and Son.)

Mrs. George Marriott (H.T.).—A very pretty Rose with yolk of egg and pinkish colouring. (S. McGredy and Son.)

Mrs. Franklin Dennison (H.T.).—A huge flower of the Mildred Grant form, with a porcelain white colouring and primrose shading at base. Exhibitors will find this a grand sort, and as it

grows so freely it must be useful, too, in the garden. (S. McGredy and Son.)

T. F. Crosier (H.T.).—A very large bloom, full, and of a soft cream yellow. (Hugh Dickson.)

Mrs. J. Sutherland (H.T.).—Excepting that it has a very dull crimson pink colouring, this should be a fine Rose, for it is quite mildew-proof and possesses the old Cabbage Rose scent. (Killermont Nursery, Bearsden.)

Flame of Fire.—A seedling Hybrid Tea of rather small size (see illustration, page 523), and specially recommended for bedding. Colour, deep orange yellow, and slightly fragrant. (S. McGredy and Son.)

Callisto (Perpetual Semi-Climber).—A nice yellow, deeper than Danæ, but not so bright,

may be acceptable to the hardy plantsman, but we fancy Rose-growers will do without them. (Paul and Son.)

The following kinds have produced flowers this autumn upon shot-out buds, and we can highly recommend them to the Rose-lover:

Constance.—Superb in its daffodil yellow colour and fine egg form, making it in this last respect a great advance on Rayon d'Or.

Hadley.—A splendid rich crimson with velvety shading. The flowers are upstanding, double and shapely, and very fragrant. There is a slight tendency to "blue" at times, but just now the colour is superb. Recently received from America.

Admiral Ward.—A very good rich reddish crimson. The buds on opening are quite blackish red, a trait the variety takes from one of its parents, Château de Clos Vougeot. The growth is erect and vigorous. We believe it will be a good addition.

Sallie.—A rich yolk of egg colouring in the centre of the flowers, which resemble Joseph Hill in form, only they are larger. The trusses of bloom are borne erect, a very excellent quality, which should make this Rose a valuable addition.

DANECROFT.

A MAGNIFICENT RAMBLER ROSE.

(AMERICAN PILLAR.)

ROSE AMERICAN PILLAR AS A WEEPING STANDARD.

and it appeared to us, as shown, not to be wanted while we have Danæ. (Rev. Joseph H. Pemberton.)

Clytemnestra (Perpetual Climber).—A very pretty mixture of apricot and reddish colouring. Doubtless very beautiful when seen growing, and, being perpetual, should be very useful. (Rev. Joseph H. Pemberton.)

Henrietta (H.T.).—If this Rose had appeared before Mme. Edouard Herriot, it would have created a sensation, for it has much of its lovely colouring, with buds not unlike Lady Battersea. (H. Merryweather and Son.)

Silver Gem.—A variegated-leaved form of some Dwarf Polyantha Rose, probably Phyllis. As shown in pots the variegation was constant, but our experience of these variegated-leaved Roses has not been very favourable. Freaks of this character

IN mid-July this charming climbing Rose is in full flower, its enormous trusses projecting out from the trellis-work and arbours, forming one of the most delightful and showy climbers of the present day. These trusses of bloom are borne on thick stems, sometimes 3 feet in length, and, unlike most climbing Roses, the flowers are not spoilt by rain and wind. The flowers are single and bright rose pink in colour, the average flower being 2 inches to 3 inches in diameter.

As this Rose is a robust grower, it cannot be given too much space in which to grow. I have known it to make shoots in one year as long as 20 feet and nearly three-quarters of an inch thick at the base.

When pruning this rambler in the winter, all the old growths should be cut out, providing there are enough young shoots to occupy the space. The new shoots should not be tied in close together; 9 inches apart will be found to be none too much when they commence to grow the following spring.

This Rose is readily propagated by cuttings taken in the autumn when the wood is ripe. When taking the cuttings, the best growths can be obtained near the base; these should be between 6 inches and 8 inches in length, and have a heel of old wood attached if possible. In fact, these can be obtained much easier if they are slipped off instead of cutting them, as they strike more readily with a heel of old wood attached than if cut otherwise. The cuttings should then be placed in a sheltered spot (better still if a hand-light is obtainable) in

good turfy loam, with about a third of silver sand mixed in it.

When these cuttings have taken root and begin to make plenty of growth, they can be planted out, and if placed in good stiff loam with some cow-manure added, they will soon become well established and amply repay for the time and labour spent on them.

F. J. CLARK.

Dropmore Gardens, Maidenhead, Berks.

AN AUDIT OF GRAPES AT THE RECENT FRUIT SHOW

ALTHOUGH there were many desirable bunches of Grapes at the recent fruit show in the Royal Horticultural Society's Hall, it cannot be said that the display was more than an ordinary one. This may be due somewhat

to the lateness in the season when the show is held, as by that time so many of the late summer varieties are past their best or have been consumed. The audit which I have compiled proves that those varieties which are of the highest quality are, naturally, the most popular, with one exception—Alicante; while inferior sorts like Gros Maroc, Gros Guillaume and Foster's Seedling are becoming almost obsolete. The total number of varieties staged—seventeen—still shows there is a hankering after a long list of varieties, which is a weakness among gardeners in the same way that it is with all fruits. Too many sorts are grown, more than their merits deserve.

Muscat of Alexandria heads the list, as it always does at this season of the year, and rightly so, as no other Grape is equal to it in all points—crop and quality. It is surprising how many years Vines of this variety will continue to bear successfully. Many comments were made at the show on the first prize award. The general opinion was that the judges were right in selecting the riper specimens. There was, in all classes, an entire absence of inferior specimens of this Grape, if there were no great outstanding bunches.

Alicante comes second in numbers, but it cannot be said there were any bunches of great merit. So many had quite small berries, while the bunches for this variety were distinctly small.

Madresfield Court was well represented in berry and colour. The bunches were quite small, but shapely.

Mrs. Pince appears to be further declining in public favour, but eight bunches were staged; these were furnished with quite small berries of fair colour.

Black Hamburgh is the most popular Grape for all purposes, especially with the amateur. October is late to see it in good condition. The six bunches shown were of a desirable character.

Prince of Wales appears to be a puzzle to growers to present it in good condition. So many growers fail to get bunches at all, while others fail to fertilise the berries properly. In the first place, new wood is necessary to produce bunches of a good size. One bunch was well presented, being of full size, with enormous berries which were fairly well coloured. The remaining five bunches were quite ordinary.

Muscat Hamburgh, the finest-flavoured Grape known, was poorly represented by four bunches. Little in their favour can be said, although two bunches secured the premier award in the any other variety class.

Appley Towers was shown but four times, which, considering this is one of the best of late Grapes, in every way was a surprise. This Grape is fast superseding Lady Downe's, which has been popular for the last sixty years.

Lady Hutt.—The four examples of this late Grape were poor representations. At Aldenham I recently saw it in prime condition. Gros Colmar, Gros Maroc, Foster's Seedling and Gros Guillaume were only twice represented. One of the bunches of the latter was huge, regularly furnished with small, well-coloured berries. The other, which was a smaller bunch, was infinitely superior, but the least said about the flavour of this Grape the better. I once saw it grandly shown as Pennington Hall Hamburgh, but under that name it did not make any headway.

A seedling was shown said to be the result of a cross between Black Morocco and Cannon Hall Muscat. To me it was much like Directeur Tisserand, which cannot be said to possess many qualities beyond a shapely bunch and highly coloured berries.

POTATO TRIALS AT WISLEY.

A SUB-COMMITTEE of the Royal Horticultural Society's fruit and vegetable committee examined the early and midseason Potatoes under trial at the Society's gardens at Wisley on July 29 and since made the following recommendations for awards, which were approved by the President and Council at a recent meeting.

PREVIOUS AWARDS CONFIRMED.

First-early Varieties.—Award of merit, given in 1908 to Midlothian Early, stock under trial sent by Messrs. Dobbie.

Second-early Varieties.—First-class certificate, given in 1912 to Whitchill Seedling, sent by Messrs. Dobbie. Award of merit, given in 1901 to Express (Sharpe's), sent by Messrs. Barr. Award of merit, given in 1900 to Sir John Llewelyn, sent by Messrs. Dobbie.

Midseason Varieties.—Award of merit, given in 1911 to Great Scot, sent by Messrs. R. Veitch.

NEW AWARDS.

First-early Varieties.—Award of merit to Duke of York, sent by Messrs. Dobbie.

Second-early Varieties.—Award of merit to Old Yellow Ashleaf, sent by Messrs. Stark; and to Stirling Castle, sent by Messrs. Sutton. Commended, General Joffre, sent by Messrs. Sands.

Midseason Varieties.—Award of merit to Arran Chief, sent by Messrs. R. Veitch; Stretton No. 20, sent by Messrs. Milne; and to Wolfe's Secundus, sent by Messrs. Dobbie. W. WILKS, Secretary.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

HYDRANGEAS AND OTHER QUESTIONS (Zitella).—Established Hydrangeas flower each year if properly treated, though a good flowering depends upon good wood being made and thoroughly matured. The best cuttings are formed of the tops of the shoots, and these, rooted in spring and early summer and grown without a check, give good heads the following season. Hydrangeas are either pink or whitish in colour naturally, though occasionally they sport and produce blue heads of bracts. The deeper colour is obtained by the use of a preparation known as Cyanol, obtainable from seedsmen and others. Sweet Sultans prefer rich, light, well-tilled soil, and they are not likely to succeed if sown in ground that was "very hard." Sow thinly in pots in October or November—half a dozen seeds in a 5-inch pot—grow in a cold frame or quite cool greenhouse for the winter, and transfer to the open in March, planting in well-cultivated ground.

ORNITHOGALUM ARABICUM (H. C. R.).—This is not suited to growing out of doors permanently, though growing plants might be plunged in a bed or border to flower. It is unreliable for forcing. Such bulbs frequently refuse to start after being collected in the wild (green) state, and fungus—the combined product of this and subsequent packing and sweating—permeating the tissues, sets up decay. It is usually of erratic behaviour. Nertera depressa has never given us the least trouble when grown in a cold frame in peat, loam and burnt earth, and abundantly supplied with water at all times other than the flowering season, when it should also be freely ventilated. Comparative overhead dryness at flowering-time must, however, be observed. The plant is quite hardy if plunged in a cold frame. Stapelia is a large and comprehensive genus, and we could not even guess the name of the species to which you refer from a verbal description. The largest-flowered is *S. gigantea* its flowers are often 12 inches to 14 inches across. This might be the one you refer to. *S. spectabilis*, *S. grandiflora* and *S. Asterias* are very large. The last named is one of the handsomest of these plants. The shedding of the flowers of *Salvia patens* and their sparse production are among the weaknesses of an otherwise glorious plant. If you are acquainted with anyone who is a Fellow of the Royal Horticultural Society, the presentation of his card would admit you to the Wisley Gardens, or you may become a Fellow by subscribing one guinea annually, which would also entitle you to other advantages.

THE GARDEN.

No. 2293.—VOL. LXXIX.

OCTOBER 30, 1915.

NOTES OF THE WEEK.

Autumn Tints.—Among the many beautiful trees and shrubs garbed in their rich autumn colour at Kew, *Parrotia persica* is very prominent. No words can adequately describe the rich colours, a gorgeous blending of crimson, orange and gold. It is a tree of moderate size for its height, and the lower branches are wide spreading. The clusters of flowers with prominent red stamens are produced during February and March. As the name suggests, this *Parrotia* is a Persian tree, and though first introduced over seventy years ago, is not commonly cultivated.

A Pure White Autumn Crocus. On this page we illustrate an autumn-flowering *Crocus* of rare beauty which recently gained an award of merit from the Royal Horticultural Society. Mr. E. A. Bowles, on page 529, writes in praise of this beautiful *Crocus*, which has cup-shaped blossoms and rounded segments of fine texture.

Antirrhinum Eaten by Animals. At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. Cuthbertson called attention to the damage done by some gnawing animal (possibly the short-tailed field mouse) to the developing fruits of *Antirrhinums* at Marks Tey, Essex. The half-ripe fruits were bitten through and either partly or wholly devoured. Only one variety had been attacked out of a great number growing there, viz., *Yellow King*.

Gall on Root of Cupressus.—To the same meeting Mr. Finlay Sanderson of Chislehurst sent a large gall (larger than a cricket ball) from the root of a tree of *Cupressus lawsoniana*. Similar galls on the roots of *Cupressus* and other plants have frequently been shown before the committee, and are probably due to the attack upon the plant of *Bacillus tumefaciens*.

Rose Cissie Easlea.—This is one of the best, if not the best of the newer varieties I planted last autumn. Its habit is very vigorous, bearing fine shoots and handsome, leathery foliage that is immune from the slightest trace of mildew, and the blooms are well held on erect stems. The colour is a pale buff, with pale carmine shading in the centre. It is a Rose that lasts well on the plant, while as a cut bloom it retains its freshness for a very long time. This is a variety that, once tried, will be always grown.—E. W.

Solidago Golden Wings.—The common Golden Rod, *Solidago Virgaurea*, would be more highly prized did it not come into bloom in July or August, when we have a wealth of Nature's best. In *S. Golden Wings*, however, we have a showy border flower blooming at the end of September, when we are inclined to be less fastidious. This Golden Rod, however, is of real intrinsic worth; it is of medium height, and its golden flowers are borne on graceful corymbs, which doubtless suggest

ing. How often, when this lovely tree is grown at all, is it huddled up among larger-growing trees, and rarely seen in the perfection it would attain if allowed the room it deserves.

Plum Coe's Golden Drop.—This late dessert Plum is not grown nearly as much as its merits deserve. Ripening in September, the fruit will hang until the end of October if the weather is not excessively wet. The cropping qualities are not excelled by any variety, seldom missing a crop if there are Plums at all. The flavour is unsurpassed by any variety, not excepting *Green Gage*. True, a wall is necessary, but it does not matter in what aspect it is planted, it is sure to succeed. The variety has been in cultivation over a century, and is the result of a cross between *Green Gage* and *White Magnum Bonum*.—E. M.

Loganberries.—I have seen good use made of Loganberries by forming a dividing line between the flower and kitchen gardens. Here, planted on soil notorious for its hungry nature, we have a long run of trees planted six years ago, and never once have we failed to get a heavy crop, and in a favourable season many plants make shoots 12 feet or more long. As it is upon these that the next year's crop is taken, readers can readily understand that a ladder has often to be pressed into service when gathering the fruit. Another very strong point in favour of the Loganberry is that birds are not so partial to the ripe fruit as they are to the smaller bush fruit, such as Currants and Raspberries.—F. R. C., Oxford.

A Beautiful Tiger Lily.—Throughout October and during the preceding month *Lilium tigrinum splendens* has been flowering freely in a bed of peat near to the Palm House at Kew. The Lilies were planted between the rather low-growing *Rhododendron Kämpferi* of Japan. This method

of growing hardy Lilies and *Rhododendrons* together has everything in its favour. The nature of the soil and the cool conditions at the root suit Lilies to perfection, while the flowers are borne well above the foliage of the dwarfier *Rhododendrons*. The variety *splendens* is probably the best of the handsome Tiger Lilies, and certainly one of the latest to flower. It grows to a height of 7 feet, and the large, orange flowers are spotted with deep chocolate, almost black spots,

AN AUTUMN CROCUS OF RARE BEAUTY: *C. PULCHELLUS ALBUS*.

its name. *S. Golden Sheaf* is also quite showy, but it is too late in flowering, in Scotland at any rate, more especially as it attains a height of about 7 feet in well-cultivated soils, and consequently suffers from the autumn winds. — CHARLES COMFORT.

The Broad-Leaved Spindle Tree.—At this season of the year *Euonymus latifolius* is very beautiful. Charming as are the other kinds of Spindle Trees, this exceeds them in brilliancy and size of fruit. The leaves also lend depth of colour-

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Crinum Powellii in a Reader's Garden.—The Hon. Mrs. Sidney Meade, Frankleigh House, Bradford-on-Avon, Wilts, sends a photograph of a well-grown *Crinum Powellii* in full flower with the following note: "It is growing in my garden, in the open air. It has been in the same spot for over twenty years, and is quite unprotected in winter. It begins to flower about May, and continues to bloom in September."

Covered Chains for Roses.—The mention by "C. G. B." of tarred rope for Roses prompts the enquiry, Why not tie rope round the iron chain? In this way we should not only have strength, but also, for those who are suspicious of its safety, dispense with any danger of the Rose growths coming in contact with the iron. I may mention that some time ago the idea prevailed here that some iron supports were adversely affecting some plants of Rose Dorothy Perkins, and good stout rope was introduced; but the fears proved a myth, and plenty have since been planted and trained "round and round" the chains without showing the slightest ill-effects.—H. TURNER, *Serlby*.

—We do not use chains covered with anything except good paint, and we find the Roses do very well. We have here a pergola consisting of three small arches, connected on either side of the path with iron chains. Over each arch we grow climbing Roses, Dorothy Perkins, Crimson Rambler, &c., and train all available shoots along the chains to connect the arches. As said above, the chains are well painted before they are put up, and the Roses, which have been planted some years now, have grown and flowered splendidly along the chains, to which they were carefully tied. The pergola was a much-admired sight this summer. We have never found the chains detrimental in the slightest degree to the growth of the Roses, though many readers have expressed surprise that we have not. But if rusty chains had been put up, we should not have had such grand results; indeed, I have seen that done in one garden, and all the young shoots were spoilt. It does not seem to matter if the chains rust slightly when the shoots are old, tough and strong; it is only the fresh young shoots that are considerably damaged thereby.—E. T. E.

A Bright Summer Border.—The *bona-fide* "ribbon border" is now out of fashion, and has sometimes been rather hardly dealt with by those whose horizon is rather narrow. I venture to opine, however, that a border—or rather a series of borders, for the entire length of 100 feet is intersected by two walks—on the roof of the Waverley Market, Edinburgh, looked very bright and attractive during the past season with the following arrangement: An ornamental railing at the back was partly clothed with the two decorative Dahlias *Souvenir Gustave de Douzon* and *Glare of the Garden*, with the following single or double lines—*Marguerite Mrs. F. Sander*, *Pelargonium Paul Crampel* (double line), *P. Harry Hieover*, *Lobelia Waverley Blue* (double line) and *Alyssum minimum*. It should be stated

that this is here the only exception to the more popular free-and-easy style of massing, and Mr. McHattie has, unknown to him, been often complimented on his defiance of Mrs. Grundy.—CALEDONIA.

Cobs, not Filberts.—In your issue for October 9, page 499, "G. G.'s" notes on Filberts were probably intended to include the Kent Cob Nuts, but they were not mentioned. Allow me as a grower of Cobs to say that either the white or red skinned varieties of the Filbert are very uncertain croppers. For example, I hired a fruit plantation for fourteen years, and only once had a crop! Therefore, except for those who can afford lean years and who fully appreciate the Brazil Nut-like flavour of a Filbert, I cannot advise their culture on a paying scale. Kent Cobs, however, seldom fail to bear, although owing to bad weather at their season of flowering—in February and March—the yield may be small. On an average they crop well four years out of five. In 1913

CRINUM POWELLII IN A WILTSHIRE GARDEN.

It has been in the same place for over twenty years.

I paid 2d. per pound to get the crop picked—only 40lb; in 1914, about 1,000lb.; 1915, nearly 2,000lb.; and I have known them retailed at 3s. per pound and as low as 3d. My plantation trees are over a hundred years old, trained in the Kentish basin shape, not over 6 feet high, and are robust and healthy now. To get the Nuts in perfection when dry in winter, soak them overnight in water. In storing in jars, add a little salt to keep them moist.—GEORGE BUNYARD.

Verbena chamædrifolia.—It may interest your readers to learn that the late Captain Saville Reid of Yalding was responsible for the reintroduction of this valuable species. It must be quite seven years ago since he wrote me that he had received from his son in South America seeds of a scarlet creeping Verbena, and that the plants had passed through the winter in Kent with him unharmed by frost. I was much interested in the plant, and could not find anyone who knew

of it in cultivation. It was introduced in 1827, and is figured in the *Botanical Magazine* about that date. Doubtless it was the parent of many of the garden forms we enjoy to-day, but none of which has the same brilliance of colouring. I showed a large mass of the variety on my wall garden at Holland House in 1913, but it was not then honoured by an award, which was a great disappointment to the late Captain Reid. He was an ardent plant-lover, and his garden was full of fine plants. He was particularly successful in the cultivation of Lilies, *L. Parryi* in particular.—R. W. WALLACE, *Colchester*.

Tree Carnations Sporting.—Last winter I had several plants of May Day, which sported and produced flowers almost similar in colour to those of the variety Marmion. I retained the old plants, and this year they are bearing true May Day flowers again. The plants were cut back late last spring. Have any readers of THE GARDEN had a similar experience? I propagated from the stems which produced the sports, but, unfortunately, lost the young plants owing to a long illness. There now appears little chance of regaining my lost sport.—SHAMROCK.

The Breaking of Darwin Tulips.—The Rev. Joseph Jacob, issue October 2, page 485, asks a few questions regarding the above, but my own experience seems to refute all theories. I grow the bulk of my Tulips—some 100 varieties of Darwin and Cottage—between the Roses. Manure they have in plenty, water in abundance. Lime, guano, &c., they must of necessity get when such are applied to the Roses. Yet last spring I lost the entire stocks of nearly a score of varieties, while many others, including the Cottage sorts Fairy Queen and Orange King, were anything but true. The breaking is not due to too frequent lifting, for bulbs in the ground for the third year broke as freely as those planted last autumn. The bitterness of it all is that the breaking is not general everywhere at one and the same time. Last spring several friends within a few miles of London, but at different points, suffered as badly as myself. A Cambridge grower informed me that the breaks were very plentiful, and a grower for cut bloom at Hythe wrote me a most despairing note about the sporting of his Darwins. Although he had grown them for years, he had never before seen a break, yet last spring his Pride of Haarlem, Clara Butt and many others simply went to pieces. On the other hand, two large growers in Essex assured me that on their heavy soil the breaks did not average half per cent. I do not know what the general view is, but it appears to me that fairly heavy, moist soil is less liable to bring breaks than the lighter, dry soils. The most mysterious feature of all is the fact that the breaking seems to be confined to the pink, red and violet shades. The yellow Cottage varieties have never shown a break with me, nor have the maroon Darwins. Equally mysterious is the fact that whereas there are no pure white Darwins, all the breaks show flakes of pure white. I might mention that in 1914 one clump of Clara Butt contained a break which showed ochrous yellow stripes in addition to red. Last spring, however, this break failed to reappear, the flakes being red on pink.—T. A. W.

Rose Corallina.—In the excellent list of autumn-flowering varieties given on page 506, issue October 16, the above-named variety is omitted, and, knowing this Rose so well, I would not like to see it omitted from ever so short a selection. Corallina was sent out by Messrs. W. Paul and Son in the year 1900. In colour it is deep rose, with a pronounced flush of coral. The buds are shapely, highly perfumed, and produced in large numbers.—E. M.

Crocus speciosus Bowles' White.—This autumn I have been enjoying for the first time the flowers of this lovely white variety of *Crocus speciosus*. It is a great improvement on the white *C. speciosus* albus as procured from the trade. The latter is invariably much thinner in substance than this handsome variety. With the exception of a passing flush of blue at the base of the exterior on first opening and a faint lining inside, the flowers are of a charming white.—S. ARNOTT.

Apple Miller's Seedling.—With reference to Apple Miller's Seedling, of which your expert pleads ignorance in a reply to a correspondent, issue October 9, page 502, there are two or three notes with respect to it in the 1908 volume of THE GARDEN. Apparently it gained an award of merit in 1906 or 1907, and is well known in the Newbury and Wantage district, where it was first raised. It is noted that few firms catalogue it, but it can be found in the list of Messrs. Jefferies of Cirencester. It is in season in August.—J. C. ALSOP, Meadowside, Marlborough.

A Remedy for Club in Cabbage.—In your issue for October 9, page 492, your correspondent "B." asks for a remedy for club in Cabbage. For several years I was seriously troubled with this fungoid disease, and, like your correspondent, tried several ways of cultivation to combat it, but with little result. A friend who tried Seride No. 1 Grade with success advised me to give it a trial. Contrary to the directions for use, and to make sure, if possible, of preventing the disease, I watered the seedling beds of both Cauliflowers and Cabbages about ten days after the plants appeared above ground, and afterwards followed the directions for use, one measure to the gallon of water. For the past two years I have continued this course, and have saved all Cabbage and Cauliflower crops. They are now absolutely free from club, and, what is much to the point at the present time, this has been accomplished at a trifling cost both in labour and material.—J. CASWELL, Piggott's Manor Gardens, Elstree, Herts.

A Twining Shrub to Name.—I shall be so much obliged if you will tell me what plant the

enclosed fruit and leaves belong to. It is a climber and is on a small pergola. The fruit is one of a cluster like a small Banana "hand."—ENQUIRER, Chilworth, Surrey. [This is a pretty twining shrub known as *Akebia quinata*. It is a native of China and Japan, and although usually given cool greenhouse treatment, it succeeds well in the open in the Southern and Western Counties of England.—ED.]

The Silk Pod Tree of New Zealand.—Can you kindly give me the name of the enclosed? I hope it may arrive in a fit state to examine, but though picked only an hour ago, it seems already drooping. It is grown from seed sent from New Zealand with the name of Silk Pod Tree, and the seed-pod is similar to that of the Cotton Plant.—A. L. FORD, Lynmouth. [The interesting

CROCUS PULCHELLUS ALBUS.

By E. A. BOWLES, M.A., F.L.S.

IF ever a plant thoroughly deserved an award of merit, *Crocus pulchellus albus* is that one, for it has almost as many good points as a centipede's allowance of legs. Chief among them, though, one should rank the fine texture and firm substance of its blossoms, as it is owing to these qualities that its whiteness is so pure and beautiful. It not infrequently happens that white forms of normally lilac flowers inherit a transparency or skim-milk effect along with their absence of the lilac pigment. This is especially noticeable in some

BORDERS OF DARWIN TULIPS FROM BULBS PLANTED IN NOVEMBER.

seed-pod sent for naming was that of *Asclepias fruticosus*, sometimes known as *Gomphocarpus fruticosus*, a small shrub, native of South Africa, growing about 4 feet high. It was probably introduced into New Zealand from there. It is a member of the Natural Order Asclepiadæ, and, like many others of this Order, produces large pods of seeds enclosed in a silky down.—ED.]

FORTHCOMING EVENTS.

November 3.—National Chrysanthemum Society. Lecture by Dr. Frederick Keeble on "The Scientific Aspects of Plant Breeding," 7 p.m. Dickens Room, Carr's Restaurant, 264, Strand, London, W.C.

November 9.—Royal Horticultural Society's Exhibition of Flowers, Fruits, &c., 1 p.m. to 5 p.m.

of the autumnal Crocuses, as, for instance, the white form of *speciosus* and that very free-flowering variety of *sativus* called in gardens var. *Haussknechtii*, both of which are flimsy and unsatisfying beside a good white variety. Possibly the best of all white autumnal Crocuses is that known as *C. marathonsius*, but it usually commences to flower so late in the season that only where its flowers can be protected by glass overhead can one enjoy them for any length of time. Now this white Crocus, that has lately been honoured by the floral committee of the Royal Horticultural Society, is generally in full bloom in the early days of October and before the rough nights have begun their ill-treatment of such dainty blossoms. The rich orange markings of the throat appear even more conspicuous in this white form than

in the typical lavender blue one, and the orange stigmata and white stamens add another charm of contrast to its beauties.

It has been collected now and again among the blue form in its homes in the Near East, the Forest of Belgrade and on both sides of the Bosphorus, and perhaps is even now being trodden underfoot by the armies at war on the slopes it inhabits. The white form was rare in cultivation until quite recently, when it has, fortunately, appeared among seedlings from the type in more than one garden.

It was a happy day for me when I first saw it in my seed-beds, some seven years since, and now I have in flower some of the children of the original albino, just as white and sturdy as their parent. For garden effect it is best to plant it alongside the ordinary form, the contrast of colouring making it appear all the more beautiful and interesting; but if a good crop of white seedlings is desired from it, it will be best to isolate it and fertilise it with pollen from the white form only.

THE LAUREL-LEAVED RHODODENDRON.

(*R. MAXIMUM*.)

CONSIDERING that this useful evergreen Rhododendron was first introduced into British gardens nearly two hundred years ago—in 1736, to be exact—it is surprising that it is still comparatively little grown. Presumably this is largely because so many beautiful hybrids have been raised in gardens, which for decorative purposes surpass the species. The most important and valuable trait of the Laurel-leaved Rhododendron (*R. maximum*) is the late season of flowering. Towards the end of June and the first half of July, when the great majority of Rhododendrons are over, the subject of this note is in full beauty. A native of the United States of America, *R. maximum* is a perfectly hardy species. In a wild state it is met with as a small evergreen tree some 30 feet or rather more in height. In this country it is a shrub 8 feet to 10 feet in height, occasionally a little taller. The leaves are narrowly obovate to oblong, 4 inches to 6 inches or rather more in length, dark green above, paler beneath. The pale rose-tinted flowers are in compact trusses, 3 inches to 4 inches across. *R. maximum* is readily raised from seeds, which ripen freely in this country. The plants thrive in the usual peaty compost to which Rhododendrons are partial, the roots liking a moister root-run than is necessary for the free-growing hybrids. Rhododendrons love moisture in the growing season, both overhead and at the roots. It may be said that the Laurel-leaved Rhododendron and its hybrids are among the most delightful of all hardy evergreen shrubs.

BERRIED TREES AND SHRUBS.

I WAS much interested in the article, issue October 2, page 482, on "Berried Trees and Shrubs." The introduction of so many new hardy shrubs from Western China, particularly of the Berberis and Cotoneaster groups, promises to make our gardens of greater interest during the autumn months. The new Chinese Berberries are a wonderful race, and if used to good effect in our gardens, will give astounding and beautiful effects. There are many forms close to the beautiful

B. Wilsonæ has been most welcome to the landscape gardener. It can be used in several positions with advantage, and, unlike many plants, produces effect the first season after planting. In France, a few years since, large quantities of this Barberry were used to carpet the ground between masses of large-spreading Junipers which had been planted on a mound crowned with tall specimen Abies. The effect in October of many hundred plants glowing with scarlet berries against the dark background of Junipers and Abies was most telling. I look forward with the hope that the species will be planted as freely in the future as, shall we say, the common Laurel has been in the past; and if "Chinese" Wilson had only introduced this one shrub, the present and future generations will be eternally grateful to him.

Other Berberises of beauty are *B. concinna*, with large, pear-shaped, scarlet berries and with the under side of the foliage quite white. *B. verruculosa* is beautiful in its compact habit and shining, deep green foliage. *B. aggregata* is of stout growth, smothered with scarlet fruits, and in the opinion of a first-class judge (I know of none better) is the best of its class. I understand *B. Veitchii* is equally good, though I have not seen it; also *B. Prattii*, young plants of which with me are very distinct. *B. sargentiana* (which received an award of merit recently) as growing here is very vigorous. It belongs to the Knightii group. The young growths are very highly coloured and it possesses most formidable spines, and, being evergreen, would be a splendid hedge plant.

Another brilliant shrub in autumn and all through the winter, on account of its fruit and foliage, is *Stranvesia undulata*, a spreading form of which I have grown for the last six years. It is now not more than 18 inches in height, covers at least 2½ square yards of ground, and at this season is smothered with clusters of berries of a particularly pleasing and distinct shade of dull orange pink. It is practically an evergreen, and portions of the foliage turn a most lovely scarlet during the winter months. Altogether it is a very beautiful and ornamental shrub. I understand the usual form of this shrub is more erect in growth.

Of the many Cotoneasters, space does not permit me to mention, except to draw special attention to the value of the creeping *C. Dammeri* for the rock garden, especially in the dull winter season. Let the growth of this species ramble near to a planting of the grey Spanish Savin, and when a midwinter sun lights on the glaucous grey of the Savin, sparkling with frost, and also on the scarlet berries of the Cotoneaster, a wonderful picture of winter effect in the rock garden is obtained.

Colchester.

R. W. WALLACE.

RHODODENDRON MAXIMUM, ONE OF THE MOST BEAUTIFUL OF ALL HARDY EVERGREEN SHRUBS.

Berberis Wilsonæ, but all more or less distinct, such as subcauliata, very vigorous, with glaucous foliage and scarlet stems covered with coral red berries; then *B. Coryi* is a tall, erect-growing species (apparently close to *brevipaniculata*) of great strength, covered with orange scarlet fruits. *B. stapfiana* is but yet little known, but may briefly be described as a sturdier edition of *Wilsonæ*. We have here another form close to *Wilsonæ*, but with very glaucous foliage, of George Forrest's collecting. This looks like making a splendid rock shrub, and its blue-grey foliage is charming. All these species, producing much fibrous root, are easily moved, and one other good point is their freedom in producing fruit. I do not know their equal in this latter respect.

THE DAFFODIL YEAR BOOK, 1915.

BY THE REV. G. H. ENGLEHEART, M.A., V.M.H.

IN a "ballad of bulbs" a recent poet in *Punch* confesses how, after adhering to a rigid economy in all other expenditure, he suddenly fell a victim to the lure of a bulb catalogue, and "bang went five shillings." Every gardener has his own best-loved flower, but the keen hunger for spring flowers is common to all. In England the Daffodil has come to be—perhaps always was—pre-eminently the flower of spring, and we shall be in sore straits when we can neither plant its bulbs nor greet its bloom. The report of Daffodil shows held "as usual" in 1915, their advertisement for 1916, and the present issue of the Royal Horticultural Society's "Daffodil Year Book" all indicate that this will be the last flower to be suppressed by the exigencies of the war.

In its first intent, and in its matter for the most part, this is a handbook for the specialist, but will be found pleasant to handle and dip into by those who dwell outside the more intimate Daffodil circle. As to its material form, binding, paper and type are of the best, as is the way it lies flat open in one's hand, as all books should, but few do. The contents and their arrangement are again good enough to reward the responsible Editor, the Rev. J. Jacob, for his great pains and to bring him our thanks. With regard to the illustrations—such a book must necessarily have them—it is as difficult to know what to say as it must have been for him to choose and prepare them. But it is probably a just criticism to prefer the personal portraits to those of the flowers. It seems that colour can be satisfactorily represented only by over-expensive colour photography, or by some method of screening in plain photography which it has here been found impracticable to use. Accurate pen and ink outlines would put the flowers before us quite as intelligibly as these photographs.

For instance, the yellow and orange red *Ixion*, Fig. 2, is shown just as white all over as Mr. A. M. Wilson's pure white trumpet *Centaur*, Fig. 4. And the four blooms of *Santa Maria*, "of an exceptionally deep yellow," are shown in Fig. 6 as four colourless ghosts. The truth is that the older line engraving, wood, copper or steel, rendered colour infinitely better than the modern photographic process. The long line of *Empress*, Fig. 12, is surely rather a dreary record of unimaginative planting.

Of the contributed papers, far and away the most interesting is "Among My Seedlings," by Mr. G. L. Wilson, a somewhat new planet in the Daffodil sky. He can write English, an accomplishment not so common as is supposed, and has a singular power of turning his pen into a "colour brush." His account of the series of choice lemon yellows obtained from a cross between *King Alfred* and *Mme. de Graaff* is admirable and very attractive, e.g., "beautiful and decorative

very pale bicolors, with trumpets of exquisite cool tints of greenish primrose and pale greenish lemon, and on the backs of their petals often the sparkling green midrib of their grandparent *maximus*." This prompts a suggestion, by the way, that we have not yet done enough—indeed, we have done nothing—at our shows to foster fine discrimination of colour. Why should we not have classes for colour simply, independently of form; for instance, a prize for the best pale lemon Daffodil? Under the present wearisome and John Bullish ordinance that no flower shall be recognised unless it has the stereotyped flat, round perianth, many and many a seedling is thrown away as too loose or starry, which massed would exhibit new and delightful colouring. Even Mr. Wilson is over-much obsessed by the flat perianth. Would he or anyone "with half an eye" think to improve *maximus* by fitting it with the regulation cartwheel perianth in place of its exquisite spiral gold petals?

and Australia is emphasised in this issue. Besides an article on the New Zealand shows in 1914 by Mrs. J. Maclean of Oamaru (who travelled over 800 miles to see the flowers), there are full reports of the Auckland, Canterbury and other New Zealand shows, and of the Australian shows. The Year Book is brimful of everything in the way of record and statistic that the Daffodil-lover needs or can do without, including the irrepressible Daffodil fly, now agreeably increased into two equally spiteful varieties, both of which are well illustrated in all their stages. Pages 32, 33, 34, *pace* the Editor, are valueless. They tabulate 172 separate crosses as "successful" because they have produced seed, thirty-nine as unsuccessful because they have not. Mr. N. Y. Lower, who contributes the figures, himself observes very truly that lists of good seed and pollen parents are not of much use, as many varieties will seed in one district and not in another; also, it may be added, in one season and not in

A BEAUTIFUL BORDER OF PHLOXES. THEY MAY BE PLANTED NOW.

The reprint of two papers read by the late Mr. Peter Barr in Australia is welcome as a remembrance of the writer, and contains much information about the earlier Daffodil scientists and growers. But 1885 is surely a mistake or misprint; it must have been fifteen years later that Mr. Barr visited Australia. Mr. E. H. Jenkins' paper, "Reminiscences," has the same kind of interest, reaching back over forty years, when Messrs. Barr and Sugden were growing the entire ancestry of our present multitude of Daffodils in a few narrow beds at Tooting. These beds are fresh in the present reviewer's memory. There is always a charm in anything that comes—and it comes too seldom—from the pen of the Royal Horticultural Society's secretary. He writes about "Three Small Daffodils," and propounds the distressing heresy that *Narcissus triandrus* and *N. t. calathinus* are "the one so much like both that you can't tell t'other from which." The rapid oncoming of the Daffodil in New Zealand

another. Moreover, insects are always responsible for a percentage of results, and flowers manage to fertilise themselves in a remarkable way, despite the most careful depollination. And it is somewhat absurd to call a cross "successful" before the seedling has flowered.

TWELVE GOOD PHLOXES.

A CORRESPONDENT asks for a list of twelve good herbaceous Phloxes, with hints on their cultivation, ten to be of salmon, crimson or pink shades, one blue and one white. These fine herbaceous flowers are best planted in the autumn, although they may also be planted in February or March, providing the soil is reasonably dry and free from frost. Phloxes appreciate a liberal diet, and with this end in view the soil ought to be dug at least two spits deep and well

NEW COOKING APPLE REV. W. WILKS.
NOTE ITS FRUITFULNESS ON A VERY
YOUNG CORDON TREE.

manured in each layer, partially decayed farm-yard or stable manure being best. Water-logged soil is fatal, and that very sandy is almost as bad, though in a different way, inasmuch as Phloxes must have plenty of moisture at their roots during the growing and flowering seasons. When the plants have been established a year, the growths, when about 4 inches high, should be thinned to three or four to each plant, the shoots that are removed being suitable for cuttings, which many contend is the best method of increasing the plants. If the lower leaves are removed and the shoots planted firmly in boxes of sandy soil, they soon emit roots if kept in a close, slightly warmed frame. These cuttings can be planted out as soon as rooted, and most of them will flower late in the autumn after the old plants have finished. The young plants last in good condition for two years more, after which, in most instances, they are better discarded in favour of younger and more robust specimens. During dry weather copious supplies of water must be afforded every day, and if this can be supplemented once a week with weak liquid manure, so much the better. There are now so many excellent varieties that it is difficult to select a dozen which would meet with everyone's approval, but the following are all first-class and reasonable in price: America, bright salmon pink, with carmine eye, 2½ feet; Baron von Dedem, rich scarlet, very large flowers, 2 feet; Dr. Königshofer, orange scarlet, crimson eye, 3 feet; Embrasement, salmon scarlet, purple eye, 3½ feet; Etna, bright orange scarlet,

3½ feet; G. A. Strohlein, orange scarlet, carmine eye, 3½ feet; Goliath, bright carmine, crimson centre, 5 feet; Le Mahdi, violet blue, suffused bronze, 3½ feet; Mme. Paul Dutrie, soft rose, white centre, 3 feet; Selma, pink, with crimson eye, 3 feet; Tapis Blanc, white, 2 feet; Gruppen Königin, pink, carmine eye, 3 feet. The heights given are only approximate; they will vary somewhat with soil, situation and weather.

NURSERY NOTES.

MESSRS. J. CHEAL AND SONS, LTD.

ON the occasion of a recent visit to the Lowfield Nurseries of Messrs. J. Cheal and Sons, Limited, Crawley, Sussex, we were most favourably impressed with the immense stock of well-trained fruit trees to be seen there. Both Mr. Alexander Cheal and Mr. Joseph Cheal, the two genial principals of this time-honoured firm, anticipate a big run on cordon, pyramid and bush trees, and, happily, they are well prepared to meet a demand even in excess of that of last year. Standard, half-standard, espalier and fan-trained trees are alike represented on a very large scale, and include every variety worth growing.

The Value of Cordon Trees.—That there should be a greater demand for cordon trees than ever is not at all surprising when we consider the many advantages of this system of training. The trees come into bearing quickly. With varieties like Rev. W. Wilks, Gloria Mundi and Charles Ross, even maiden trees are often so heavily cropped that their fruits have to be considerably reduced. Then, again, cordon trees may be successfully grown in a limited space, and when trained upon wires or against a wall or fence they take up little room, and, unlike standard trees, they do not overshadow the garden at the expense of other crops. Pears and Apples are well adapted to this system of training, while Red Currants and Gooseberries may also be grown in this way with marked success.

Apple Crawley Beauty.—If there was one variety more than any other that attracted our attention by virtue of its bright colour and very heavy crops, it was this excellent late-cooking Apple of local origin. Like the Wise Apple, it is very late in flowering, thereby escaping injury from late spring frosts. In consequence, those who have grown it regard it as a certain and heavy cropper. The fruits hang upon the trees quite late in the season, and when stored they will keep till April or May. The shapely fruits are splashed with crimson, and they are even better in colour than Bismarck, while it crops heavily on young trees. Two other local Apples worthy of special mention are Nanny and Jolly Miller, both carrying exceptionally heavy crops of highly coloured fruits. Neither of them appears to be very well known outside the county of Sussex, but both are worthy to be in every collection.

Redwing is another favourite Apple at Crawley. It is a brilliantly coloured, medium sized fruit, in season in October, and is useful either for dessert or cooking purposes.

Exigencies of space prevent us from enlarging upon the fine stock of Pears, Plums, Damsons, Cherries, Peaches, Currants, Vines and other fruits, to say nothing of a vast collection of trees and shrubs, which have always been a feature of this firm, so long renowned for landscape gardening.

THE RASPBERRY-BLACKBERRY HYBRIDS.

BY EDWIN BECKETT, V.M.H.

WITHOUT doubt many of the hybrid and improved varieties of the Rubus family will play a very important part in the future in supplying the population with wholesome fruit.

It has long been a surprise to me that more encouragement has not been given in relation to the extended cultivation of even the common English Blackberry, when one considers that it grows luxuriantly in almost every locality and under the poorest conditions; that there is always a ready sale for the fruit, and, fortunately, that it is one of the fruits which adapts itself for preserving in many ways. But at the moment my thoughts are centred on the newer varieties, several of which are, I feel certain, destined to take positions in the majority of our English gardens. Fortunately, the majority lend themselves readily to cultivation in many ways. They are excellent for covering pergolas and arches, poles or pillars, and for training on buildings, or planting in large beds, and if judiciously pruned

A CERTAIN CROPPER. APPLE CRAWLEY BEAUTY.

and trained once a year, beyond regulating the growth and protecting the fruit when ripening, this is practically all the labour required. I propose to mention only a few of the best varieties which have come under my notice.

Blackberry Himalayan Giant.—A large and much-improved form which certainly strikes me as being the finest of its kind which I have yet seen. It is very vigorous and most prolific, the growths being covered with immense trusses of large, black, beautiful fruits which commence to ripen about the middle of August. The fruit when

and Raspberry Superlative. It is of fine appearance, of rich flavour, partaking much of that of the Raspberry. It is rather pendulous in habit, and succeeds best when trained to stakes or trellis. It grows freely on almost any soil, and, fortunately, is a perpetual bearer, commencing to ripen its fruits early in the season and continuing to do so till late in the autumn.

The Loganberry.—Too well known to need describing. With us it does splendidly, planted in large masses in the wilderness, and the fruit

purposes, several of them being extremely vigorous and producing large fruits, but, unfortunately, the flavour of the majority is poor and insipid.

AN IRIS FOR THE WATER-SIDE.

IRIS SIBIRICA can be depended upon to grow and flower freely if planted about the margins of lakes, ponds or streams where the roots are continually moist, and there are few showier subjects when it is at its best during early June.

THE SIBERIAN IRIS BY THE LAKESIDE AT KEW.

thoroughly ripe is of a delicious flavour, and quite worthy of a place as a dessert fruit. Messrs. Laxton Brothers of Bedford worthily received a first-class certificate for this Blackberry at one of the Royal Horticultural Society's meetings during the present season.

Newberry.—This variety has done remarkably well with us this year. Growing on a west border and trained like the Raspberry, it produced a wealth of luscious fruit much superior, in my opinion, to that of the Loganberry.

The Laxtonberry.—This most promising variety is the result of a cross between the Loganberry

is much appreciated for cooking purposes. It preserves splendidly.

The Lowberry.—This is another hybrid possessing much merit. It should be grown in full sun and be severely pruned.

King's Acre Berry.—This ripens early and has the appearance of a very large Blackberry. It has a very fine flavour.

Many of the new varieties of *Rubus* introduced from China by Mr. Wilson are extremely ornamental, but are of little use for commercial purposes. I am inclined to think, however, that these will make excellent material for hybridising

Throughout the growing season the grass-like leaves present a pleasing change from coarser vegetation, whereas the tall, slender flower-scapes, growing to a height of $2\frac{1}{2}$ feet or 3 feet, terminated with lilac purple or bluish flowers, are most attractive.

Added to this, it gives comparatively little trouble, for, once established, it grows for several years without attention other than keeping it clear of coarse weeds. When the clumps become overgrown, they are easily put right by dividing up into smaller sections as soon as the flowers fade.

MY COTTAGE GARDEN IN HAMPSHIRE.

A TINY plot of under half an acre all told, in a Hampshire hamlet, and as I look from the little lattice window over a dream of "Carnation, Lily, Lily, Rose," I can hardly believe that less than two years ago a very different view met my gaze—two square beds of decayed vegetables edged with long-neglected herbaceous borders, and divided by a gravel walk that ran up the entire length, disappearing in a ditch of Ferns, through which a neighbouring broom-maker, bent nearly double with his ninety odd years, peered through from his own small plot at this scene of desolation. The cottage was commonplace and ugly, the garden an uninterrupted dead level from end to end, but for a bank that ran down the side of the plot separating it from the beautiful Pine

A TRANSFORMED COTTAGE AND GARDEN.
The pathway is flagged with York stone squares and bordered with Lilies and Roses.

wood beyond, and which was a thing of beauty, pale gold and thick with Primroses and Daffodils, and in this I had my dream!

It did not take long to transform the dwelling, but the garden was a question of patient care and attention through the first winter months, and also not a little artistic selection in planting.

And let no one think that many hands combined to make this labour light. To an old villager whose "rheumatiz" was, alas! more regular than his hours of labour was allotted the spade work, while the rest was a labour of love divided.

It may interest some to know what this tiny place contains; and that it is laid out to some advantage the accompanying illustration may prove.

All the paths are flagged with York stone squares, through which peep the modest Violet

Cress, red and white Mossy Saxifrages, and Linaria; and Alyssum Little Dorrit scrambles defiantly up and down and in between the stones, throwing up fairy bushes of snow. To relieve the long straight line, the path is partly sunk, and a circle made where an old sundial is to be placed "when the war is over." I should like its shadowy finger to mark that date of Peace for the world for all time, and never to move again! (But I have yet to find the dial, and they are luxuries these hard times.)

The rustic arch across the path further on is still gay with the cerise blooms of Rose Zephyrine Drouhin, and the light square trellis which runs right across the garden at right angles and encloses a tiny rosary beyond still holds blooms of Rêve d'Or, Mme. Pierre Cochet, Gastave Regis, Perle d'Or, Félicité Perpétue and Stella.

At the end of the garden the ancient neighbour has been excluded by a high double hedge of Arbor-vitæ and Taxus baccata, which successfully hides from his inquisitive gaze the rosary, in the centre of which stands a fine old stone bird bath, a permanent invitation to the feathered intruders who certainly preside over this little garden. Someone has written that "a pleasure garden, however small, should have its presiding genius, its nymph of the pool, the woodland, the grove or the well, to give a personal interpretation to the forces of Nature," so that the piece of sculpture here placed is surely a necessary adjunct and gives a last touch of colour in the picture. The grass plots are broken up with Rose beds to form a uniform design, and have been gay all the summer with Lyon Rose, Mme. A. Chatenay, Elaine, and such old favourites as Warrior, Irish Elegance, Earl of Pembroke and Caroline Testout. Two narrow beds in front of the window are still a mass of bloom of Mrs. W. H. Cutbush and Aschenbrödel, all planted where but a little more than a year ago flourished the Potato and Turnip of commerce at their own sweet will.

On either side of the long flagged path and edging the lawns are the herbaceous borders, backed with tall Larch posts for Ramblers, placed at intervals of about 8 feet apart. These borders have been a succession of bloom, from the cloudy, early effect of London Pride, Myosotis, Clove Pinks and Thrift to Delphiniums in their heavenly blues, and perennial Asters in purple hues.

The cottage itself hides behind a Vine on the south-east side, planted many years ago; and on the south, Rose Fortune's Yellow, Mme. Alfred Carrière, and Clematis Viticella kermesiana, with its lovely trails of wine-coloured flowers. The more familiar Jackmanni has hung its deep purple-blue blooms over the bay window ever since June in a dense mass.

The north side of the cottage is given over to the growing of Gooseberries, Currants, and the few vegetables required for the modest household of the present owner, a musician who can delight huge audiences in London, and who spends her precious hours of rest in the "garden that she loves."

B. L. S.

CHARITY BEGINS AT HOME

BY THE REV. JOSEPH JACOB.

"CHARITY begins at home" is one of those proverbial sayings the truth and appositeness of which no one, theoretically at any rate, disputes. When, however, the opportunity comes of putting the sentiment into practice, a red herring is sometimes drawn across our purpose and we go and do otherwise. By means of a very considerable advertisement in the papers, the Horticultural Trades Association of Great Britain and Ireland has lately given us a jog about this, with regard to the buying of bulbs. The Editor of THE GARDEN has asked me to "say a few words." I gladly do so, for I am pleased to do my "bit" for our common cause in any way I can, and I am more than glad that, unlike one of the great dailies, which refused the advertisement, *our little paper* has a fellow feeling for our own horticulturists, many of whom have been very badly hit indeed by the war. In a way, I am an amphibious sort of person, or a sort of father confessor, and in writing the concluding words of the last sentence I was only saying that which I personally know to be a fact. Our growers must somehow keep on growing, for bulbs and plants cannot just be put on one side and not used. Our retail traders have working expenses going on all the time, and they have to provide for a custom which more likely than not has never come. In war-time, if ever, our highest and soundest policy is to remember that "charity begins at home." Misplaced sympathy is one red herring. There are others. First, the old idea that all Dutch-grown bulbs are better than British. On the very afternoon of the day on which the Editor asked about this article, I met a friend, who, knowing nothing whatever about what we had been saying, told me, in the course of ordinary conversation, of a neighbour who had within the last week sent an order for nine pounds' worth of bulbs to Holland, *because they were so much better than he could get at home.*

It may have been necessary for Henry VIII.'s last queen, Catherine Parr, to send over there for her salads. Why, however, do some people in the present year of grace think they must follow her example in order to get good bulbs?

With the exception of Hyacinths, all the great popular spring, summer and autumn flowering bulbs can be produced quite as well within the narrow confines of our islands as anywhere else. I feel sure our growers would be doing themselves and the country a real good turn if they were to hold a show of their own home-grown produce in late July or early August next year. A high official of the Royal Horticultural Society has been approached, with the result that he has said that if the idea is taken up by those who are in a position to support it, and if they will undertake to send samples of what they can do, he has every reason to believe that the Council will provide all necessary facilities. Accordingly, I appeal to all growers, great and small; to those who live in Anglesey, Jersey and Guernsey, no less than to the dwellers in Great Britain and Ireland, to "take the matter up." Write your ideas about this at once to THE GARDEN, and I can promise that if support is forthcoming, "the powers that be" shall know of it.

In these months of stress, no false scent should be allowed to turn us from the right way.

NOTES ON VEGETABLES.

ONE of the most valuable ingredients in successful vegetable culture is what is known as decayed vegetable refuse added to wood ashes, old potting soil, road grit, decayed leaves and spent Mushroom-bed materials. Where the soil is heavy, it is not so porous as other soils, but with the aid of deep

ROSE LEAF ATTACKED BY BLACK SPOT.

trenching and the annual addition of the compost noted, it is surprising how quickly a bad plot can be brought into a desirable condition. For Potatoes especially is such a compost valuable; indeed, it is difficult to suggest a crop which it will not benefit in some way or another. Now is the time to collect a quantity of vegetable refuse. All leaves of the Brassica tribe should be collected into a heap, adding freshly gathered leaves and wood ashes, occasionally turning over the heap and adding at that time freshly slaked lime.

Fallen leaves, too, should be collected and kept in a heap by themselves, to be used in the making of hotbeds or for conversion into leaf-mould, which is valuable to mix with soil of an uncongenial character when pricking out seedlings.

Autumn Onions now a couple of inches high would be all the better with the surface soil stirred during dry weather, first sprinkling soot over them and the soil. If the latter is heavy, add wood ashes, as these have an ameliorating effect when applied to the surface and gradually mixed with the soil about the roots. The main crop of summer-grown bulbs should be examined, assuming they are in a dry shed. Remove any loose skins and roots, and either string them on ropes or lay them thinly on shelves in a cool, dry room.

Turnips.—Bulbs which are of full size from earlier sowings should be lifted and stored in sand or ashes at the back of a wall with a northern aspect, covering the outside with long litter or leaves in case of frost. Stir the surface soil among

growing crops and, as a protection, draw soil over the crowns of the bulbs. This preserves their succulence as well.

Beetroot should be lifted and carefully stored in sand in a frost-proof shed, cutting off the leaves to within 2 inches of the crowns.

Parsnips should remain in the ground until required, drawing soil over the crowns to protect them from frost, as this is liable to rot that portion. If severe frost is apprehended, cover them with litter as well as the soil. A few for immediate use may be taken up and stored in sand.

Swanmore.

E. MOLYNEUX.

BLACK SPOT ON ROSES.

[A Reply by Mr. Edward Mawley, V.M.H., President of the National Rose Society.]

IT will be exceedingly interesting if Rose-growers among your readers who have had any experience of black spot in its virulent form will state whether they have met with any success in dealing with this scourge. It is only, I imagine, during the last two or three years that its ravages have been so serious. Is it confined to certain districts—the West of England, for instance—or has it spread all over the country? It is not only that the bushes become leafless, in a greater or less degree, but the growth is stunted and the weaker plants die away. I find all sorts of Roses are attacked. The Pernetiana and Austrian Briars are most susceptible, but Hybrid Perpetuals are no more immune than Hybrid Teas, Chinas and Noisettes. Among those that suffer most severely are Juliet, Lyon, Grüss an Teplitz, Snow Queen, Francesca Kruger, Lady Roberts, Soleil d'Or and Marie Baumann. With regard to treatment, I found this year that Bordeaux mixture was absolutely useless. It was given a complete and thorough trial.

I agree with your correspondent "T. A. W." that it will be most interesting to hear what Mr. Edward Mawley has to say on the subject. And one would much like to know the later experiences of Mr. Darlington, who contributed to the Rose Annual for 1914 an exceedingly valuable article on the subject full of interest. H. V. B.

We forwarded our correspondent's letter to Mr. Edward Mawley, V.M.H., President of the National Rose Society, who kindly sends the following reply:

"This is a comparatively new enemy of the Rose, and is supposed to have come to us some years ago from the other side of the Atlantic. It is only in recent years that it has made its appearance in my own garden, where, however, it has gradually secured a footing. As stated by correspondents in recent issues of THE GARDEN, it has a great partiality for certain varieties, such as Grüss an Teplitz and Juliet. I have up to the present time kept black spot in check by simply removing, as far as possible, every leaf on which the disease made its appearance, and by picking up and burning all fallen foliage which is affected. In this way I have managed to keep the complaint fairly well in check. Nevertheless, every year a few more plants fall victims to it than in the previous year. I can, therefore, only recommend at this time of year the removal of the worst of the affected leaves found on or under the plants and burn them, and then at the end of the flowering season to do the same.

"I wish I could afford better help, for I can plainly see that my own Rose garden is not nearly as badly

overrun with black spot as that of either of your enquirers, "H. V. B." and "T. A. W." In fact, not more than 5 per cent. of the Roses in my collection is affected. What I have stated may, however, be of service to many of your readers. I have heard of several remedies being suggested, but have not myself tried any of them, and cannot report on them from personal experience. I feel sure, however, that many of your readers would be glad to learn of any fungicide which could be depended upon year after year to keep a Rose garden now badly affected with black spot free, or, at all events, comparatively free, from this new and destructive enemy of the Rose. It is therefore to be hoped that this correspondence in THE GARDEN may lead to some simple and really effective cure of this cruel disease in our Rose gardens being communicated to its pages."

RUST ON ROSES.

THIS disease is prevalent on Briar Roses. It is caused by the fungus *Phragmidium subcorticatum*, and its first appearance is quite early in the season, in the form of bright orange masses of spores bursting through the bark. They leave cankerous-looking spots on the stems, and, being carried to the foliage, attack it, producing orange or brown and in autumn black spots on the under surfaces of the leaves. These spots are small masses of spores, for the fungus is out of

ROSE LEAF AND LEAFLET ATTACKED BY "RUST" DISEASE.

reach inside the leaves. Something may be done by spraying with Bordeaux mixture or with a rose red solution of potassium permanganate in the spring at the time the stem stage is about; but the main thing to do is to destroy the dead leaves on which the black spore masses occur in autumn as soon as possible, and so prevent the infection in early spring, which comes only from these black spores. This fungus is very common on Dog Roses in our hedges.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Forcing Strawberries.—Gardeners are sometimes called upon to produce ripe Strawberries in February. The first consideration must be the ripening of the crowns. If there is any doubt about them being well matured, they should be left in their summer quarters as long as the weather will permit. About the middle of November they may be placed in a shallow, heated pit. If convenient, a hot-bed of moderate warmth should be made in which to plunge the plants, and this must be elevated quite near to the glass. For the first two or three weeks a temperature of 45° or 50° will be quite sufficient. This can usually be maintained without the aid of artificial heat. Fire-heat must be used sparingly at all times.

Plants Under Glass.

Roses in Pots.—The present is a suitable time to procure Roses for growing in pots. A few of the climbing varieties should be potted annually, as these are invaluable for furnishing the conservatory or show houses in the spring. The following varieties are all suitable for this purpose: Dorothy Perkins, Minnehaha, Hiawatha, Blush Rambler, Goldfinch and Electra. Of dwarf varieties there is now a wide selection, but it is best to have a few reliable sorts, especially if flowers are needed for table decoration. Mme. Abel Chatenay, Mrs. J. Laing, Liberty, Richmond, Kaiserin Augusta Victoria, Sunburst and Lady Hillingdon are all excellent for this purpose. Some of the strong roots must be shortened before potting. Use a compost of loam, leaf-soil and lime rubble. If the loam is poor, add a little crushed bone and soot. When potted, plunge the pots in ashes in a sheltered situation.

Roses Planted Out.—Roses growing over the roof of the greenhouse or conservatory will now be in need of pruning or thinning. This must be done more or less according to the variety. In all cases the flowering wood must be well exposed to the light. The variety Fortune's Yellow often makes a lot of lateral growth, which requires to be cut back to one or two buds. The roots should still be given plenty of water, which must be supplemented occasionally with a stimulant.

Freesias.—A batch of Freesias may now be placed in a light house with a little warmth. Place them on a shelf near to the glass, for they must not be allowed to become drawn at this stage. The pots will now be full of roots, and a little stimulant will be beneficial. An occasional weak dose of soot-water will be sufficient for a week or two.

Achimenes.—These will now have died down, and the pots may be placed under the stage in a cool house. Lay them on their sides so that water cannot reach them.

Forcing Shrubs.—There are many beautiful shrubs suitable for forcing, and the present is the most suitable time for potting them. Such plants as Laburnums, Lilac, Prunus triloba, Staphylea, Viburnums, Spiræas, Cerasus and Pyruses may be dug up and potted in any ordinary soil. When potted, plunge them in ashes till they are required for forcing.

The Flower Garden.

Montbretias.—The corms of Montbretias should be lifted annually and wintered in boxes of dry soil in cold frames. Lift them as soon as the foliage has died down, or the corms will start to grow. It is necessary to separate the small bulbs from the large when planting. If required, the small bulbs may be planted in reserve beds, where they will grow to the flowering size.

Gladioli.—Corms of Gladioli may also be taken up and stored in a frost-proof shed. They may first be placed closely together in boxes till the foliage has died down. They must then be cleaned, carefully labelled, and stored away for the winter.

Early Flowering Chrysanthemums.—There are many good varieties of Chrysanthemums suitable for growing outdoors, and the best only should be retained. When these have finished flowering, they must be lifted and planted closely together in boxes, carefully labelling each variety.

Place the boxes in cold frames till the spring, when they will be required for propagating.

Lawns.—Any alterations to lawns may be done when the weather is suitable. New turf laid now will be quite settled by the spring. If worms have been troublesome on tennis lawns, they may easily be destroyed now, as they are quite near the surface. Lime-water is cheap and effective. This should be applied in the afternoon.

The Hardy Fruit Garden.

Root-Pruning.—The season has been favourable for ripening the wood on all fruit trees, and, where necessary, the sooner the work of replanting and root-pruning is done the better. In planting new trees on walls, the old soil should be cleared out and replaced with new. If the subsoil is heavy and retentive, plenty of drainage materials should be placed under the new soil. A quantity of old brick rubble must be mixed with the new materials. If the loam is good, no manure of any kind is necessary. This can be given later on when the trees are in bearing.

The Kitchen Garden.

Onions.—The bulbs must be carefully looked over at intervals for the removal of those which are blemished. The whole of the stock should be moved, and those which are not likely to keep must be placed by themselves for immediate use.

Celery.—The late plants must be earthed up as required, but it is not wise to do this to excess till there is danger of very severe frost. Much care is necessary in doing this work now, so that the soil does not fall into the centre of the plants.

Turnips.—The roots which are large enough for use may be lifted and stored in a shed, or, failing this convenience, covered with ashes outdoors. Later crops must be left in the ground till there is danger of severe frost.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Flower Garden.

Lobelia cardinalis.—In the more favoured districts this brilliant subject is more or less hardy, but undoubtedly the safest method is to winter it in frames. If put in boxes, it will be more convenient for starting in springtime. On no account try to increase it at this season by division, as it resents disturbance until growth has recommenced during the spring, when it splits up quite freely.

Violas.—Except in very severe or wet weather, the lights may remain off for some days yet. Weeds and decayed leaves should be picked off, as, where these remain, damping is more likely to take place. When the lights have to be replaced, ventilate on all mild days, only closing them when the frost is severe. Avoid coddling in any form, as the Viola is a very hardy subject under natural conditions.

Flower Beds and Borders.—Where there is no spring bedding, the vacant ground should be cleaned and made tidy for the winter. Digging and, where necessary, trenching should be done, so that the soil will derive all the benefits from being exposed to the frost and rain of the coming winter.

Sweet Peas.—The sowing of the autumn seeds in pots for flowering next summer should be completed before the very short days approach, as, if sown then, the germination is not nearly so strong. Ventilate freely and apply water only when really needed.

The Rock Garden.—Protect now with glass those subjects which are known not to survive when left exposed to the winter rains. Many of the plants should not have their foliage cut down, as is sometimes practised. It is in many plants a fine and natural form of protection from both rain and frost.

Fruit Under Glass.

Pot Strawberries.—The young plants having now completed their growth for this season, there is nothing to be gained by leaving them in their present position. Some growers place

the plants on their sides and stack them with ashes around the pots; but as they cannot be watered in this position, harm would come from it through the plants becoming too dry during windy weather. The best method is to plunge the pots up to the rims in ashes inside cold frames; but where these are not available, protect with 5 inches or 6 inches of freshly fallen leaves. Care must be taken that the foliage of the plants is kept above and not buried when plunging them.

Vineries.—Midseason Vines should be given every encouragement to ripen their wood, so that it will be possible to get pruning over in good time, and the houses cleaned early to enable the Vines to have quite three months' rest. This resting period is very important, and where it is not given strict attention, the Vines quickly show the ill-effects by poor growths and consequently poorer fruit crops.

Plants Under Glass.

Cyclamen.—Plants commencing to flower should have frequent applications of manure given in the water. Weak soot-water is very suitable if not overdone. Plants raised from seed sown in August will soon be ready for potting off singly into 3-inch pots. Use plenty of leaf-soil and coarse silver sand in the compost when doing this. Seed may still be sown for producing useful plants which will flower in 4-inch pots during next winter.

Poinsettias.—The bracts of these plants are already forming, and it is from this stage onwards that great care is necessary in watering and in the maintaining of even temperatures if the foliage is to be retained. The atmosphere must now be kept somewhat drier, but a minimum temperature of 60° should be maintained. The same treatment applies to Euphorbia jacquiniæflora, but this plant is usually a month later in flowering.

Lilium Harrisii.—As the bulbs commence to grow, remove them to a position near the glass, where a sturdy growth may be expected. Grow in an intermediate temperature, and do not top-dress until the roots commence to appear above the bulbs. Keep a constant watch for green fly, and spray with an insecticide on its first appearance.

Protection of Plants Outdoors.—Such plants as Azaleas and Roses, which were perhaps forced and plunged outdoors to complete their growth, should now be grouped closely together, and a depth of 6 inches or 7 inches of new leaves laid on to protect the pots from becoming cracked by frost. Care should be taken to see that the roots are sufficiently moist before covering with leaves, as then they will need no further attention until taken indoors.

The Kitchen Garden.

Lettuce.—Any blanks which have occurred among those recently planted out should be filled with the surplus seedlings remaining in the seed-bed. If slugs are troublesome, a dusting of soot should be given; or, if the weather is very wet, some gritty material, such as sharp sand, must be applied. This does not get washed into the soil so quickly as soot.

Radishes.—Further supplies will now have to be obtained by sowing either in heated frames or pits. For economising space the seeds should be sown broadcast, thinning out the Radishes as required for use.

Mustard and Cress will now have to be grown in heat to make certain of a regular supply being kept up. Sowing thickly in boxes is the most convenient method, and placing over pipes, where germination quickly takes place. To have both ready for use simultaneously, the Cress should be sown three days previous to the Mustard.

Weeds.—Every opportunity should be taken to rid the garden of as many weeds as possible before the very wet weather in winter commences. Where annual weeds have not reached the seeding stage, they can be dug into the ground without any fear of reappearance at some future time.

Mushrooms.—Beds must be regularly made up whenever sufficient material for making them has accumulated. Those which are made up and spawned at this date will produce Mushrooms from Christmas onwards. The temperature in the Mushroom-house should not be allowed to exceed 60°.

JOHN JEFFREY.

PLANTING FRUIT TREES.

BY GEORGE BUNYARD, V.M.H.

AS November draws near, a few practical hints on this subject may be helpful to intending planters. Where possible, it is best to plant before Christmas, but the work can also be done successfully up till April, when the soil is friable. Owing to the war, some delay in transit must be expected in the delivery of orders this season, but no harm can come to packed fruit trees. Should the roots be dry and the shoots shrivelled on arrival, an immersion in water for twenty-four hours will plump them up, and in most cases where the roots only are in water.

Distance to Plant.—In order to allow for extension, the different forms of trees should be planted as follows: Standards in gardens, 24 feet; standards in orchards, 18 feet in grass; espaliers and wall trees, 15 feet apart; cordons, which, by the way, do as well upright as on angle, 2 feet apart; bushes to form "basin" trees, 12 feet apart; pyramids, 10 feet, or 5 feet to start, taking one out when needed; Gooseberries and Currants, 6 feet apart; Gooseberries and Currants (cordons), 1 foot apart; Gooseberries and Currants (if trained), according to form. On walls there will be spaces between the fruit trees for flat trained Currants or Gooseberries for a few years, while Tomato plants can go on the south walls between the trees.

Thinning the Fruits.—When Apples and Pears are the size of a Nutmeg, it is best to thin the fruits where they occur in bunches to one or two fruits, and to regulate the fruits well over the whole tree. In this way all the fruits produced will be of a nice size and be of better quality than where the trees are overloaded. Trees that crop heavily should be mulched in May with half-rotted manure, and be watered in dry weather. Where manure is not available, half a pint of Clay's Fertilizer sprinkled over a circle of 4 feet across round the stem and then hoed in will be beneficial, watering it in from time to time. No manure should be given to trees without fruit, as it only encourages them to form wild wood. Fuller information can be found in the admirable and concise directions given in the pamphlet, "Hardy Fruit Trees," which can be had in return for 2d. stamps from the Secretary, Royal Horticultural Society, Vincent Square, Westminster, London, S.W.

After Unpacking, examine the roots and cut away any damaged ends; and as it is the surface roots which are the most valuable, any strong roots which point downwards should be shortened to 6 inches from the main bulk of roots; then dig a hole 2 feet over and 1½ feet deep, and below this break up the soil, make a little mound in the centre of the hole, and place the tree upon it. Begin to fill in, raising the upper roots as the work of filling in goes on. Gently press down each layer of roots, giving the tree a little upward shake as each layer is completed. Before finally filling in, observe the earth mark on the stem of the tree, and let it appear an inch above the level for standard, espalier and wall trees; then firmly tread the soil in the hole. On the top of this firm soil lay some fine soil, and the work is done, except that in some cases a stake may be needed to steady the tree. Bind some old sacking or straw where the tree is tied to the stake, to prevent rubbing of the bark. Note,—The ordinary

soil of a garden is rich enough for any fruit trees, and no manure is needed at this stage. Now, in the case of cordon, pyramid or bush trees which are worked on Paradise stock for Apples and Quince stock for Pears, *it is most important to let the junction of stock and scion be 3 inches under the surface*, otherwise growth will be checked.

If planted before January, bushes, pyramids and standards may be pruned back, say, to 6 inches beyond the two-year growths; but cordons and espaliers are best left to be regulated in the summer. Wall trees, such as Plums and Pears, if fan-trained, may have their young shoots cut back to a foot of the two previous years' growth; but horizontally trained wall trees are best left unpruned.

If any ill-placed, strong shoots appear on the cordons or espaliers in the following summer, they had better be left till August 1 before removal. At this time any spray or thin shoots in the centre of bush or pyramidal trees should be shortened back to four leaves, and spur-pruning should take place; that is, on the boughs several shoots may start which are not needed, and they should be cut back to four eyes to form fruiting spurs in the future, but leave the "leader" shoots the full length. This keeps up a flow of sap and strengthens the shoots cut for spurs. These leaders should be cut back to 6 inches in March; but in no case should the leaders of cordons be cut back, unless bare spaces occur, as it is often difficult to get a good lead afterwards.

Do not let the jobbing gardener plant your trees unless you superintend the work, as he comes under Kipling's words in his poem, "The Glory of the Garden":

"And some can pot Begonias and some can bud a Rose,

And some that can't be trusted with anything that grows."

In planting Raspberries the roots must not be deeper than 4 inches, and the canes must be cut back to a foot to induce spawn canes to throw up for the next year's fruiting.

Gooseberries should be cut back freely in planting, also Red and Black Currants. They will then form strong shoots to make nice basin-shaped trees. Both Red Currants and Gooseberries can be spur-pruned in; but Black Currants fruit on the young wood, and must be left the full length, merely cutting out year by year the old shoots that have fruited. By doing this the berries will always be large, and not hard and full of seeds. The summer pruning of Red Currants and Gooseberries is done in July after the fruit is gathered, the object being to get spurs on the main branches, and, as with Apples, &c., the leader shoot is left full length, to be cut back in March to extend the bushes 6 inches a year until they are large enough. All these bush fruits can now be supplied as flat trained trees for trellises or as cordons, from which fine fruit is taken. Gooseberries fruit on the young shoots, and, if desired, the strongest shoots can be left full length, merely cutting away ill-placed shoots and keeping the bushes thin in growth, as only poor berries will be produced if the bushes are a mass of useless wood.

For the guidance of amateurs I now give a select list of those fruits which do well, as a rule, in any form, all being free bearers of good quality.

Apples for Eating.—Early: Gladstone, Lady Sudeley and Ben's Red. Midseason: James Grieve, Allington Pippin and Cox's Orange Pippin. Late: Cockle Pippin, Baumann's Red Reinette and Sanspareil.

Apples for Cooking.—Early: Victoria, Grenadier and Golden Spire. Midseason: Rev. W. Wilks, Warner's King and Lord Derby. Late: Newton Wonder, Bismarck and Alfriston.

Pears.—Early: Colmar d'Été, Beurré d'Amanlis and Doyenné Boussoch. Midseason: Conference, Louise Bonne of Jersey and Emile d'Heyst. Late: Durondeau, Doyenné du Comice and Belle Julie.

Plums.—Early Prolific, The Czar, Denniston's Gage, Jefferson Gage, Victoria and Belle de Louvain.

Damson.—Bradley's King.

Cherries are of little use in villa gardens, but Morellos make fine bushes and are indispensable for north walls.

Black Currant.—The Boskoop.

Red Currants.—Dutch and Knight's Sweet.

White Currant.—Dutch.

Raspberries.—Superlative Red and White Antwerp. Autumnal: The Alexandra.

THE CHRYSANTHEMUM AND ITS ASSOCIATIONS.

THE first of the series of educational lectures organised by the National Chrysanthemum Society for the season of 1915 was delivered on Monday, the 4th inst., by Mr. Harman Payne at Carr's Restaurant. The title was "A Chat about the Golden Flower: Its Poetical, Mythical and Romantic Associations." There was a good attendance, especially of ladies, and the meeting was presided over by Mr. Thomas Bevan.

Except for a short interval in the middle, the lecturer discoursed for about two hours on the various curious and interesting stories, myths and legends pertaining to the Chrysanthemum in the Far East. Interspersed with these were some translations of Chinese and Japanese poems relating to the flower. The audience listened with the greatest possible interest to the lecturer's remarks, and frequently expressed their appreciation of the way in which the subject was dealt with. It was quite out of the ordinary run of a horticultural discourse, and was practically a literary effort which displayed an amount of research in a field little dreamed of by those present.

There was a large number of lantern slides shown, many of them quaint and original, not the least interesting being those that depicted some of the effigies and mythical scenes from Japanese stories built up with living plants of Chrysanthemums by the clever florists of Dangozaka. Beginning with Confucius and ending with Dr. Neesima, the first Christian teacher of Japan, who introduced Mrs. Alpheus Hardy, the famous hairy Chrysanthemum, into America, the story told by Mr. Harman Payne was one of absorbing interest.

The next lecture will be by Dr. Keeble on November 3 at the same place. Mr. Percy Cragg gives the final lecture on December 8.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

PÆONIA OFFICINALIS LOBATA (C. S.).—This beautiful Pæony was figured in Sweet's "British Flower Garden" as long ago as the year 1838, and although in cultivation since that time, does not appear to have become common in gardens. It is of the same habit as the type, growing 18 inches to 2 feet high, and produces elegant, almost cup-shaped flowers of a rosy pink shade.

VARIOUS QUESTIONS (A. K.).—The Sweet Williams should be quite good for another year, and had they been divided and replanted after flowering, would have shown an increased vigour. The seed may also be sown at once in the open; the seedlings will provide excellent plants in due course. The Deutzias should have been pruned to near the ground weeks ago; it is late for such work now, as no new growth that would be of service could follow before frost arrived. In any case, however, the pruning might be risked, with transplanting and division, if possible, into a richer soil. Yes, the Persian Cyclamen are those grown in the greenhouse. Follow the instructions given in the article referred to. Seakale is benefited by light dressings of salt twice or thrice yearly, and one might be given now. Liquid manure or mulching with manure may be given with advantage, the latter preferably in autumn, the former from October to March inclusive. We could not say what has caused the Currant bushes to be stripped of their leaves without seeing them or knowing more about them. It is probably the work of a caterpillar, but of this there should be evidence at first hand.

GROWING ALPINES (X. Y. Z.).—Ordinary kitchen garden soil will require much preparation before it is suited to growing alpine, unless you elect to grow only the more vigorous types, e.g., Aubrietias, Arabis, the big-leaved Saxifrages, Adonis, Arnebia, alpine Phloxes, Hepatica, the free-growing Bell-flowers and the like. The fact that it is also fairly heavy should cause you to concentrate your attention on such as we have named. Your enquiry, however, concerns the soil and preparing it for planting with alpine. As it is kitchen garden soil, it is doubtless rich in humus, a condition which will require modification. The best way to do this would be to apply to the surface a considerable dressing—it will hardly be possible to overdo it—of grit, leaf-mould and old mortar in mixture, incorporating it with the first 6 inches of the staple soil. This dressing might extend to a foot in thickness if the material is obtainable. If not, any very sandy, poor, or even stony soil would make a good substitute. You do not say whether you intend growing alpine in conjunction with rockwork or not, but if so, and the arrangement took the form of a rockery border or "flat" rockery, the stones should be first placed in position and the lighter soil added subsequently. By this means the need of adding soil to the whole area would be averted. As you do not contemplate planting before next spring, there is ample time for preparing the soil. Meanwhile, a heavy dressing of lime should be first applied to the surface. As you suspect insect life, gas-lime would be best, forking it in and allowing the ground to lie idle for a few weeks. If this is not available, secure fresh lime, put it down in mounds of two bushels each, and cover it with soil to slake it. This done, it should be spread thinly and dug in at once. The lime you refer to, if air-slaked, would do, but would be less effective by reason of age. If it has been exposed to rains it will not be of much use. The gas-lime above named should not be used unless a considerable depth of surface soil is to be added subsequently, and a lapse of at least four months should be allowed between the time of application and planting. Otherwise it might prove injurious to the plants.

TREES AND SHRUBS.

BEECH TREE STOOL (A. M. C., Okehampton).—The stump and roots of the Beech will gradually decay. Unlike an Elm, the Beech does not throw up numbers of suckers. To prevent shoots starting round the base of the stool, chop off as much of the outer bark as possible with a hatchet. To hasten decay, bore six holes 2 inches in diameter and 9 inches deep, spread over the surface

of the stool, put saltpetre to a depth of 3 inches or so in the bottom of each, fill with water, and plug with wood. The roots in the Azalea bed can do no further harm.

LAVENDER FOR PROFIT (Herbal).—The essentials to the cultivation of Lavender for profit are cheap land and a soil that is light or sandy, or light loam overlying chalk. Comparatively poor, stony soils are also well suited to it; but in heavy, retentive clay the plant is less responsive and good, also less productive. As the chief source of income would be from the flowers—though much money might also be made by raising young plants in quantity for sale—cheap land is a necessity, since few other crops could be grown in its company. In short, it is best to cultivate it apart from other things. For this purpose a good strain of *Lavandula Spica* is the best, though some of the dwarf French forms are earlier in flowering, and welcome on this account. Quantities are disposed of annually in all our larger markets when the plant is in flower, and much is used also for purposes of distillation. While one of the most popular plants, we should not consider it a particularly profitable one to grow unless under the above-named conditions.

KITCHEN GARDEN.

CUCUMBERS DISEASED (A Surrey Beginner).—The Cucumbers are suffering from an attack of Cucumber scab. Probably the house has been subject to fluctuations of temperature and the ventilation has been at fault.

CELERY DISEASED (A. B. Walford).—The Celery is attacked by the Celery leaf-spot fungus, *Septoria petroselinii* var. *Apii*. This fungus has been very abundant during late years, and is best kept in check by spraying with Bordeaux mixture at intervals of three weeks or so from May onwards. The seed is very frequently infected, and the disease is distributed from place to place by means of infected seed.

TO PRESERVE RUNNER BEANS (Pickles).—Select young, tender pods, place in boiling water with a little salt for about three minutes, after which carefully pack in suitable bottles, fill with hot water and a little salt. Then stand them in the boiler in water of the same temperature as that put into the bottles, place rubber rings, lids and clips on the bottles and bring to boiling heat, which should ensure them being airtight.

CELERY LEAVES DISEASED (J. W. Young).—The Celery is attacked by the Celery leaf-spot disease, due to the fungus *Septoria petroselinii* var. *Apii*. Destroy all badly affected plants by burning them. Do not permit them, or refuse from the plants, to find their way to the rubbish heap. Spray the remainder with Bordeaux mixture. It is almost too late this year to do this, but it is well to remember that the disease is frequently spread by the seed, which is often infected. As this is the case, care should be taken to get clean seed, and as a precautionary measure spray with Bordeaux mixture from mid-May onwards.

POTATOES DISEASED (H. T. G.).—The Potatoes are attacked by the common Potato scab bacillus, which does no harm whatever to the tubers, except that it spoils their appearance somewhat. The disease is only skin deep, and attacked Potatoes appear to be rather more mealy than those which are free. The tubers may be used next year for seed, and if it is desired to kill the parasite they may be steeped, before sowing, for about twenty minutes in a solution of one pint of formalin to two hundred gallons of water.

MISCELLANEOUS.

LEAVES SENT FOR EXAMINATION (E. T. Lightfoot).—There is nothing wrong with the Poplar or Ivy leaves, while the injury to the Oak leaves is due to a fungus, *Capnodium quercinum*.

NAMES OF PLANTS.—*Boris*.—*Helxine Solierolii*, a Corsican plant.—*M. J. C.*—A form of the Scotch Elm or Wych Elm (*Ulmus montana*), probably the variety *purpurea*.—*E. H.*—1, *Sedum spectabile*; 2, *Veronica Teucrium* var. *dubia*; 3, *Aster Novæ-Angliæ* var. *pulchellus*; 4, *Viola cornuta*; 5, *Helianthus multiflorus* fl. pleno; 6, *H. rigidus* variety; 7, *Erigeron multiradiatus*.—*D. F. G., Ivybridge*.—*Sollya heterophylla*.—*Lady Muriel Close*.—1, *Cratægus coccinea*; 2, *Cotoneaster humifusa*.—*G. Y., East Yorks.*—1, probably *Chlorophytum elatum*; 2, *Aspidium angulare acutum*; 3, *Escallonia macrantha*; 4, *Pyracantha crenulata*; 5, *Acer palmatum*; 6, *Prunus pissardi* (*P. cerasifera* var. *atropurpurea*).—*Bolney*.—1, *Rhus Toxicodendron* (Poison Ivy); 2, *Verbascum Blattaria* album; 3, *Ptelea trifoliata* (Hop Tree); 4, *Veronica angustifolia*.—*F. W. W.*—1, *Leucophytum Brownii*; 2, *Lantana salviifolia*; 3, *Begonia maculata*; 4, probably *Eriobotrya japonica* (Loquat); 5, probably a *Crinum* species; 6, *Begonia* species—propagated by cuttings, store in cool, dry house; 7, *Cissus discolor*.

NAMES OF FRUIT.—*R. A.*—Pear—*Olivier des Serres*; Apples—1, *Bowhill Pippin*; 2, *Dutch Mignonne*.—*Farmer*.—1, *Striped Beaufin*; 2, *Gold Medal*.—*Dunkerry*.—The Pear is true to name, and is *Louise Bonne* of Jersey. —*W. H., East Sheen*.—1, *Beauty of Kent*; 2, *Cellini*; 3, *King of the Pippins*. Pear decayed. —*G. B. E. R., Shrewsbury*.—Apple *Withington Filbasket*.—*E. W., Surrey*.—1, *King of the Pippins*; 2, *New Hawthornden*; 3, *Wellington*; 4, *Yellow Ingestre*; 5, *Wealthy*; 6, *Blenheim Orange*.—*E. H. C. T.*—1, *Bismarck*; 2, *Brown Beurré*; 3, *Beurré d'Anjou*. —*W. F. M. C.*—The Pear is *Marie Louise*; the other should be root-pruned. —*G. Massie*.—1, *Beurré d'Amanlis*; 2, *General Todleben*.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

THE ordinary fortnightly meeting of the society held on the 26th inst., if not characterised by the fulness of some of the gatherings immediately preceding it, was not without interest, variety or beauty. For example, fruit exhibits were of a seasonable nature, their high excellence but a further tribute to British horticultural skill, to which we have before referred. The Bunyard collection of Pears—some seventy or eighty sorts—was one, in some respects, of the finest ever staged; while the collections of fruit from Welwyn and Hampton afforded proof of the attention paid by cultivators to this department of horticulture generally. In other directions the group of rock and other shrubs from Colchester was of much merit. The early *Chrysanthemums*, too, joined forces with the last of the *Dahlias*, and afforded evidence of the waning days of the year. Orchids were not largely shown, and hardy plants were practically nil. Few novelties were on view.

FRUIT AND VEGETABLE COMMITTEE.

Present: J. Cheal, Esq. (chairman), and Messrs. W. J. Jefferies, W. Bates, Edwin Beckett, J. Udale, H. J. Wright, A. Bullock, G. Reynolds, Owen Thomas, E. A. Bunyard, J. Jaques, J. Harrison, W. S. Rivers and W. Poupard.

Without doubt the collection of Pears from Messrs. George Bunyard and Co., Maidstone, was the most interesting and instructive exhibit of the meeting, some seventy or so varieties being staged. The collection was arranged on an exceptional plan, groupings being made of those raised in France, Belgium and England, the order mentioned being also indicative of the countries providing the greater wealth of these fruits. France obviously has been ever to the front in these matters, and some of the best kinds have been raised there. In addition, the date of introduction and, in most instances, the raiser's name were given; hence in a dual sense the objects of an exhibition such as this were well served. From the French set we selected *Beurré Alexandre Lucas* (1871), *Marie Benoist* (1863), *Doyenné du Comice* (one of the finest Pears, 1849), *Duchesse d'Angoulême* (1809), *Fondante de Thiriot* (1858), *Duchesse de Bordeaux* (1850, one of the best late Pears), *Roos Nolt* (of brilliant colour and recent introduction), *Beurré Superfin* (1846), and *Catillac* (one of the best stewing Pears, 1665); from Belgium, *Durondeau* (of fine colour and first class for dessert, 1811), *Glou Morceau* (one of the best late varieties for dessert, 1759), *Emile d'Heyst* (1847, a good late sort), *Beurré Diel* (a well-known Pear, 1810), and *Josephine de Malines* (good late, 1830); in the English set, *Pitmaston Duchess* (1865), *Conference*, *Uvedale's St. Germain* (1698), *Glastonbury* (origin unknown), and *Knight's Monarch* (1838), as those that appealed most. The dates in parentheses indicate the year of introduction.

An exhibit of vegetable produce to demonstrate possibilities in times of need came from Messrs. Sutton and Sons, Reading. Sown in the open at the beginning of August and given ordinary attention and cultivation, it afforded evidence of a high order of utility that could not be gainsaid. In an extensive collection we noted Carrots of the Short and Long Horn sections, Onions, Beet, Potato Warwick Castle, Turnips, Peas, Kohi Rabi, Beans, Cos and Cabbage Lettuce, Spinach, various saladings and much besides. We have never before seen such a remarkable collection of garden produce grown in so short a period and in such high excellence. Needless to say, the collection was most attractively staged, and in this connection was a source of inspiration and instruction to many.

Mr. J. A. Nix, Tilgate, Crawley, exhibited an excellent table of fruit, Apples being the chief, though Pears and Grapes were abundant and of high quality. Of the latter, Mrs. Pince, Lady Hastings, Gros Maroc (of fine finish) and Appley Towers were all good; while *Muscot* of Alexandria was above the average. Pears *Doyenné du Comice*, *Marie Louise*, *Durondeau*, *Beurré Bosc* and *Brockworth Park* were all excellent. Of Apples, *Nancy Jackson*, *Bramley's Seedling*, *Warner's King*, *Gascoyne's Scarlet*, *Newton Wonder*, *The Queen*, *Coronation*, *Peasgood's Nonsuch*, *Lord Derby*, *Hollandbury* and *Jubilee* were among the best. A Hogg Memorial silver-gilt medal was awarded.

C. A. Cain, Esq., Welwyn, Herts, showed a superb table of Apples and Pears, for which a silver-gilt Hogg Memorial medal was awarded. The fruits were of high quality throughout, though we select *Pears Pitmaston Duchess*, *Uvedale's St. Germain*, *Emile d'Heyst*, *Conference*, *Durondeau*, *Marie Louise* de Uccle and *St. Luke*; and Apples *Warner's King*, *Rev. W. Wilks*, *Peasgood's Nonsuch*, *Emperor Alexander*, *Bramley's Seedling*, *Charles Ross*, *Lord Derby*, *Lane's Prince Albert* and *Newton Wonder* as the best in a very fine lot.

Mr. Will Tayler, Hampton, showed excellent Pears, Apples and Grapes in pots, the former including *Beurré Diel*, *Beurré Clairgean*, *Doyenné du Comice*, *Josephine de Malines*, *Durondeau* and *Beurré Hardy*; while of Apples, *Jubilee* (fine yellow colour), *Bismarck*, *Allington Pippin*, *Cox's Pomona*, *Lane's Prince Albert*, *Annie Elizabeth*, *Lord Derby*, *Cox's Orange Pippin*, *Newton Wonder*, *Charles Ross*, *King of the Pippins*, *Worcester Pearmain* and *Hollandbury* were some of the best. This was a collection of all-round excellence, for which a silver-gilt Knightian medal was awarded.

ORCHID COMMITTEE.

Present: J. Gurney Fowler, Esq. (chairman), Sir Harry J. Velth, Sir Jeremiah Colman, and Messrs. Stuart Low, F. J. Hanbury, Pantia Ralli, A. A. McBean, W. Cobb, J. Charlesworth, J. Cypher, H. G. Alexander, Arthur Dye, C. H. Curtis, S. W. Flory, W. Bolton and Gurney Wilson.

THE GARDEN.

No. 2294.—VOL. LXXIX.

NOVEMBER 6, 1915.

NOTES OF THE WEEK.

National Chrysanthemum Society's Lectures Postponed.—The lectures which were to have been delivered before the members of this society on November 4 and December 8 by Dr. Keeble and Mr. P. A. Cragg respectively have been postponed in consequence of the new lighting regulations in London.

Pinus with Juvenile and Mature Foliage.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Messrs. Cheal exhibited a plant of *Pinus Pinea* about 3 feet in height bearing both juvenile and mature foliage, the juvenile form being present on shoots at the base and near the top of the tree. Sir Daniel Morris had recently noticed a similar thing on large trees of this species near Bournemouth, and it not uncommonly produces them when cut back.

Antirrhinums Eaten by Animals.—I was greatly interested in the paragraph in "Notes of the Week" of last week's issue *re* "Antirrhinum Eaten by Animals," having suffered a very heavy loss last winter of a frame of seedling Antirrhinums by field mice. They were nibbled quite close to the boxes at our sports ground, Chingford. The shoots, from 1½ inches to 2 inches long, were buried in a corner of the frame, presumably as a winter store. I have also lost complete boxes of *Lobelia* from the same source, while Stocks and Asters remained untouched.—T. BAKER, *Hon. Secretary, Waterlow and Sons', Limited, Amateur Gardeners' Association.*

Rose Iona Herdman.—Those who are looking for a Rose for decoration in a cut state, either for vases or the dinner table, should procure this seedling, sent out by Messrs. S. McGredy and Son in 1914. I know of no variety that embraces so pleasing a tint of colour—a pure clear orange flame with a flush of ochre in the young stage of development, which adds a charm to the colour as a whole. The blooms, like those of many other charming varieties for decoration, are none too full, even when fully open; but if caught in the bud and three parts open state, then one has a Rose unsurpassed in form, colour and effectiveness.—E. M.

A Beautiful Guernsey Lily.—On page 545 the Rev. Joseph Jacob asks, "Are Guernsey Lilies coming into favour?" and to this we reply, "Unquestionably they are." Nearly all Daffodil-growers, besides others, are now taking up Nerines. Below we illustrate *Rotherside*, well known as one of the most beautiful Nerines in cultivation, and introduced by Messrs. Herbert Chapman, Limited, Rye. The flowers of this exquisite novelty are a rich orange salmon, and in bright sunlight there is a delightful scintillation on the petals which reminds one of the effect of sun rays through a stained glass window. It is a strong

other St. John's Worts, it thrives best in a fibrous loamy soil.

Plum Coe's Violet White Gage.—This is a desirable companion to Coe's Golden Gage, and might easily be put down as a sport from Coe's Golden Gage, as it possesses all the characteristics of that variety except in colour, which is shaded purple. In flavour it is similar, yet not quite equal. In ripening and keeping it is a facsimile, and in the manner of cropping and adaptability to various sites it is a desirable variety to cultivate by those who require a coloured, high quality dessert Plum in October.

Lithospermum prostratum.

Among the plants which so frequently favour us with late bloom must be placed *Lithospermum prostratum*, one of the really invaluable rock plants, and also of supreme value on a wall. To see a sheet of its dark green leaves spangled freely with its lovely blue flowers is to witness a sight to gladden the heart of the flower-lover. It matters little whether the plant is of the typical *L. prostratum* or of that lovely variety *Heavenly Blue*. Either will afford the keenest delight in October in a good season. It is of easy culture, as a rule, but sometimes old plants look shabby after a fickle winter. In this case they may be cut back, and will generally recuperate in a short period.

Coronilla glauca.—Of the various Coronillas in cultivation, this is undoubtedly the best. At the present time it is again furnishing a mass of

THE NEW NERINE ROTHERSIDE. FLOWERS RICH ORANGE SALMON.

grower, producing dense heads of flowers. On an average there are as many as thirteen flowers of unusual size and substance to an inflorescence, each flower having long, protruding anthers and delicately twisted petals.

A Little-Known St. John's Wort.—*Hypericum Ascyron* has large, rich yellow flowers 2½ inches across. A native of North America and North Asia, it is a semi-herbaceous species, the stems dying down annually to the ground. These are erect, some 30 inches to 3½ feet high, terminating in a corymb of showy flowers at their best in September. Seeds are freely produced, this forming a ready means of increase. Like

its bright yellow and fragrant blooms, which are very effective at this period of the year. A few isolated specimens in close proximity to the rock garden, or in the shrub border, would be sure of a welcome. It grows from 2 feet to 4 feet high, and the foliage is glaucous, as indicated by the specific name. Propagation is effected by division in the spring, and cuttings of young wood will root at almost any time if inserted in sandy soil and placed in a cold frame. Seed is occasionally produced, and when procurable it may be sown directly it is ripe. The Pea-shaped flowers of *C. glauca* are very numerous, and the same remark applies to *C. valentina*, which is also in flower.—B.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Plants for the Water-side.—The charming illustration in your issue of October 30, page 533, shows a pleasing display obtained from good masses of *Iris sibirica* and wild Roses when grown along the water's edge; but few readers may be aware of the beautiful effect obtained by growing *Lychnis Flos-cuculi*, the Ragged Robin of our meadows, among Siberian Irises. Both delight in such a position, and the loose terminal panicles of rosy red flowers of the *Lychnis* harmonise with the blue of the Irises.—P. G. F.

October - Flowering Rock Plants.—I was interested in the list of alpine plants given by Mr. E. C. Howell on October 16, and perhaps the following list of plants which were in flower at Castleford, Chepstow, on October 17 may be helpful to some readers of THE GARDEN who are taking

Rose Number dated October 23, page 523: *Queen of Fragrance* (Messrs. W. Paul and Son), the newer *Colcestria* (Messrs. B. R. Cant and Sons), Mrs. G. Norwood (Mr. Elisha J. Hicks), Edward Bohane (Messrs. S. McGredy and Son), Juliet, Mevrow Dora van Tets (Messrs. M. Leenders and Co.), Mrs. Frederick W. Vanderbilt (Messrs. S. McGredy and Son), Mrs. Frank Bray (Messrs. Alex. Dickson and Sons), and Melody (Messrs. Alex. Dickson and Sons), not forgetting Edward Mawley, quite one of the most fragrant.—E. M.

The Japanese Windflowers.—I have been interested in the recent notes on these flowers. In my border I have big clumps, four years established, of the varieties *Whirlwind* and *Queen Charlotte*, also of the common white, alba, and the variety *rosea*. *Whirlwind* and *Queen Charlotte* are certainly very strong, the flowers being well over 4 feet above the ground, but the blooms certainly do not compare with the others for size and effectiveness. *Whirlwind* is very free, but the blooms are small and far less impressive

It is now quite 27 feet high, and the trunk measures 2 feet 1 inch in circumference at 3 feet from the ground, and at the present time looks quite happy. I may add it is sheltered somewhat from the south and south-west winds, although exposed to the north and east. *E. globulus* is also planted out and grows to fine trees, but the wind serves that variety rather badly and causes a great amount of trouble in staking and tying. Other varieties we have are *E. resinifera*, *E. Camboges*, *E. amygdalina*, *E. coccifera*, *E. robusta* and *E. ficifolia*, all of which we have raised from seed. Most of these have been planted out for from one to three years. Although, in some cases, they have not made much growth, they have proved their hardiness in this favoured locality, and I think if they are given better positions than some of them are in at present they will grow away into good specimens.—R. H. LEGG, *Melksham House Gardens, Melksham*.

Changing the Botanical Names of Plants.—If your correspondent "H. P.," page 516, issue October 23, would acquaint himself with the rules adopted by the International Botanical Congress at Vienna, he would see, I think, that there is no contradiction in saying that the correct name of any plant is that which was first given to it, and that in certain circumstances botanists are justified in changing the name. For instance, it is not difficult to imagine cases where fresh discoveries show that a plant formerly regarded as an outlying member of one genus is in reality typical of a whole group of plants, so different from all others as to merit a generic name. Rules have been agreed upon which govern the changes involved, but the changes themselves are none the less necessary. Again, has your correspondent reflected on the consequences of the general adoption of his wish that names considered by some to be "totally inappropriate" should be dropped? I do not, of course, mean that I should say that *Magnolia grandiflora* has to me a foetid smell; but I do know that, whereas I personally rather enjoy the scent of *Fritillaria imperialis*, there are many who dislike it. If, therefore, I had been the fortunate discoverer of this fine plant, I might easily have recorded in its name the scent which to me is pleasant. Others would think it "totally inappropriate"; and who is to decide questions of taste and smell? The only logical course seems to be to admit the claims of priority, even at the expense of having occasionally to tolerate a seemingly inappropriate name. With Mr. Bean's opinion of the American and Continental hair-splitters I am personally entirely in agreement, as I think I have shown in dealing with the particular genus of plants with which I am best acquainted; but at the same time I am equally conscious of the difficulties that result from including a large number of forms under one specific name. On the whole, however, it seems sounder to define a species as liable to variation within certain limits than to take one specimen, describe it minutely with accurate measurements, and then insist that every variation from that type is worthy of specific rank. The latter is, of course, by far the easier and, at the same time, the less intelligent plan. The minute description of one specimen is a mere mechanical exercise for the trained botanist, but to know the limits within which seedlings of any particular plant may vary implies a far more extensive and intimate knowledge of the plants than most professional botanists have of those which they describe.—W. R. DYKES.

ACHILLEA KELLNERI, A LATE-FLOWERING ALPINE WITH WHITE FLOWERS AND SILVERY GREY FOLIAGE.

up the fascinating work of rock gardening: *Abelia chinensis* (syn. *A. rupestris*), *Achillea Kellneri*, *Buphthalmum salicifolium*, *Coronilla glauca*, *Campanula muralis*, *C. garganica hirsuta alba*, *C. Stansfieldii*, *Convolvulus mauritanicus*, *Caryopteris Mastacanthus*, *Cyclamen neapolitanum*, *Chenostoma hispida*, *Erigeron mucronatus*, *E. Quakeress*, *Erica vagans*, *E. v. alba*, *Erodium amœnum*, *Gaura Lindheimeri*, *Geranium prostratum*, *G. sanguineum*, *Hypericum fragilis*, *Oenothera pumila*, *O. riparia*, *O. mexicana*, *Origanum Tournfortii*, *Primula Poissonii*, *Plumbago Larpenæ*, *Parochetus communis*, *Polygonum vacciniifolium*, *P. Brunonis*, *Salvia patens alba*, *Saxifraga Fortunei*, *Silene tommasiniana*, *Satureia montana*, *Sphæralcea munroana* and *Zauschneria californica*.—T. W. B.

Fragrant Roses.—The Rev. David R. Williamson should include without delay the following varieties for their fragrance, which are, with two exceptions, a long way ahead of any he names in the

than the common white. *Queen Charlotte* is a washy colour, and the crop is never abundant. On the other hand, *rosea* simply smothers itself with bloom of much greater size and richer colouring. Moreover, its semi-double character makes the flowers much more lasting, so that I have decided to dispense with *Queen Charlotte* and increase my stock of *rosea*.—T. A. W.

Eucalypts for English Gardens.—In your issue of October 9, page 496, a very interesting article appeared on "Eucalypts for English Gardens," by Mr. E. A. Bowles, in which he gives his experience in the growing and culture of many varieties; and, as he rightly says, they give a great amount of interest and pleasure and look so beautiful in a garden among and backed up by other trees in sheltered positions. In the gardens of The Cottage, Porlock Weir, West Somerset, a residence of Mr. G. W. W. Blathwayt, there is a fine specimen of *E. beauchampiana*, which was obtained from Treseder of Truro and planted out of a 4-inch pot in November, 1908.

LILIUM SULPHUREUM GROWN BY A READER IN BRITISH COLUMBIA.

Liliums and Gladiolus tristis.—I enclose a photograph of *Lilium sulphureum* showing two spikes, the taller being $7\frac{1}{2}$ feet and carrying nineteen perfect buds and flowers. Last season the same larger inflorescence bore fifteen flowers. These bulbs are growing in the open ground, and receive no water other than that which comes from the clouds. A more majestic Lily would be hard to find, but I cannot induce it to produce seed. *L. Sargentiae* (which appears to me to be so close to *L. sulphureum* as to be merely a form of the same) seems to have no objection to bearing fat (and full) seed capsules, while *L. nepalense* has set a large number also. Can any reader furnish a description of what is to-day being grown in English gardens under the name of *Gladiolus tristis*? What I grow here has creamy, greenish-tinted flowers, odourless during the day, but powerfully scented at night, the foliage resembling that of *Iris tuberosa*, but darker green and hard, the flower-spike emerging therefrom at about 12 inches from the ground. It flowers with the latest Daffodils. A contemporary in the United States gives *G. tristis* as having tan-coloured, drooping flowers. — GILBERT ERREY, *Victoria, British Columbia*. [The photograph of *Lilium sulphureum* is abundant evidence that the bulbs are growing under genial conditions. It matters but little that *L. sulphureum* does not mature seeds freely, as bulbils are freely produced in the axils of the leaves. With us *L. Sargentiae* flowers at least a month earlier than *L. sulphureum*. In colour it is creamy white, whereas *L. sulphureum* is a decided yellow, with a much longer tube and more substance in the flower, also taller in growth. At present, except in the sunny South and West, where *L. sulphureum* does well, *L. Sargentiae* promises to be a better border Lily for British gardens. Our correspondent's description and photograph fit *Gladiolus tristis* as grown in this country. Colour descriptions of different writers are

frequently variable, and this may be the cause of the discrepancy that is pointed out.—ED.]

Cottage Garden Societies and Vegetable Shows.—I cannot agree with Mr. James Smith's letter in your issue of October 16, page 505, wherein he expresses such a poor opinion of exhibitors on the score that they are not cropping their ground to the best advantage. I should like to say that my society has about forty members, all hard-working men, and I say the more the men show, the more the garden must produce. Moreover, the vegetables are of superior quality and something to be proud of when grown. We started our usual monthly meetings last October and paid 1d. a point on all produce that gained it. We had a box on the table for those who chose to contribute; the lowest collection was 3s., the highest 8s. 7d. This money was sent to the British Red Cross and Belgian Relief Funds. At the annual show on August 4 we made every effort, paid the usual prize money and sent the balance, £12, to the Belgian Relief Fund, and 6cwt. of the vegetables were given by the members to the Fleet. We have started the same methods again this season, and in addition we have decided to send a box of vegetables each month to the Fleet. The members with families have enough vegetables for their own needs and to spare, and if Mr. Smith and his society, with their intensive culture, can make it clear that theirs is a better method than ours, I will ask his humble apology. — G. ANDREWS (*Chairman*), *Tilmanstone Cottage Garden Society*.

Late - Flowering Alpines.—I was much interested in the list of these given by Mr. E. Bowell of Cheltenham, but was rather surprised by his omission of a few other late flowerers of outstanding merit. Take, for instance, *Verbena chamædrifolia*, of which, fortunately, you had a capital illustration and valuable note in the same issue, thus more than atoning for its omission. It is a really good plant for summer and autumn flowering. Every growth bears a head of glowing scarlet flowers, and, being a trailer, individual plants will easily cover a circumference of 2 feet from the centre. *Wahlenbergia vinæflora* is likewise admirable for continuous flowering, and, very graceful, too, the flowers being borne on thin wiry stems about a foot high. Another lovely trailing plant in full flower with us is *Parochetus communis*. This bears a Pea-shaped blossom of a pleasing blue shade, while the foliage is of Shamrock type and prettily marked with brown blotches. Yet another subject that always blooms right on until it is too cold for the buds to unfold is *Oxalis rosea*. Though this plant has been flowering for many weeks past, it is still a mass of spikes; but, alas! many of these can never open owing to the fast declining sun power. *Erigeron mucronatus* has also still a nice show of flowers, and some seedling plants of *Tunica rosea* are making a fine display, though the old plants have passed their best. The treatment probably accounts for the late blossoming of the seedlings. They were sown twelve months last June or July, wintered

in a cold frame, and planted out in the spring. —C. TURNER, *Highgate*.

Aster Amellus King George.—In mentioning three outstanding *Amellus* Asters, Mr. F. J. Townend overlooks the new *King George*, which easily stands head and shoulders above all others in this section. A magnificent grower of medium height, it bears huge trusses of mid-blue flowers of wonderful size. This variety gained an award of merit last year from the Royal Horticultural Society.—T. A. W.

Antirrhinums as Bedding Plants.—Several years since in a Hertfordshire garden two beds were planted with Intermediate White *Antirrhinum*. The seed was sown in February, the young plants pricked out into a cold frame when large enough to handle, and planted out at the end of May. These beds were always admired, and although situated near beds containing a variety of more gorgeous subjects, we found that visitors made more enquiries respecting the cultivation of the *Antirrhinums* than of any other plant. Some admire these plants, but hesitate to use them in beds, fearing that they will not give a succession of flowers. We find that, providing a moderately rich soil is secured and the seed-vessels removed regularly, a display is maintained continuously throughout the summer months. As border plants, few subjects prove more useful. Many of the varieties are excellent for introducing into various colour schemes. The flowers are also useful for cutting.—C. RUSE.

FORTHCOMING EVENT.

November 11 and 12.—Chrysanthemum Show. First day, 12 a.m. to 5 p.m.; second day, 10 a.m. to 5 p.m. Royal Horticultural Hall, Vincent Square, Westminster, S.W.

ERIGERON MUCRONATUS, SHELTERED BY ROCKS, STILL PRODUCES ITS DAISY-LIKE FLOWERS.

MORE ABOUT THE ROSE GARDEN OF EUROPE.

[BY THE EDITOR, HERBERT COWLEY.]

IT came as a pleasant surprise, and at the same time a source of gratification, that my impressions of Bulgaria, published in our Rose Number, dated October 23, should have created such widespread interest. I have been asked by many readers for what reason the notes were signed "C. Q.," and in reply can only say that I employed the pseudonym under which I have for years contributed to these pages.

Fields of Fragrant Roses.—Early next morning we were again in the Rose fields. Every opened and half-opened flower is gathered when the early morning dew is on them. There were Roses everywhere as far as the eye could see, and the air was laden with the fragrance of the Damask Rose. The scene was almost equal to that at Kazanlik—the centre of the attar industry. A bevy of plum-eyed maidens, in picturesque costumes, left their baskets of Roses and gathered round my friends from Ireland. Like the older men and women, they were affable and good-natured, and at all times only too ready to pose before the camera. The peasant folk, on learning that we were Britishers, would come forward and

Saxifraga rotundifolia, *Rhus Cotinus*, *Lilium Martagon*, *Pulmonaria rubra*, *Campanula velutina* and *Pinus Peuke* (the Macedonian Pine). At higher elevations we found *Dianthus microlepis* and its white variety, *Gentiana verna*, the violet-flowered *Primula deorum*, *Soldanella montana* and *S. pusilla*, Junipers, Crocuses and Orchids in variety. Annual Larkspurs and Love-in-a-Mist abound in the lowland fields. It was while crossing the Shipka Pass that we gazed upon one of the most glorious floral sights that we could ever hope to see. Under the partial shade of Junipers and other low-growing trees were masses of that lovely *Gesnerad*, *Haberlea rhodopensis*. Its flowers were so abundant that its foliage was almost hidden from view. My late and esteemed friend C. F. Ball of Glasnevin delighted the company by discovering among rocky boulders a pure white form of this beautiful plant.

A few eagles were hovering at a great height over precipitous rocks and inaccessible places along the Balkan Range; and we learned from two Bulgarian shepherd boys that their sheepfolds were occasionally disturbed by nocturnal visits from bears.

A few years ago the Bulgarian peasants could not speak too highly of the English. They knew that the independence of their country was the work of English hands and English hearts.

Now a bewildering change has overtaken the people of Bulgaria, and they are driven by a German monarch into war with the very nations who gave them freedom from the cruel oppression of the Turks. For a wild pledge of empire the peasants have betrayed their traditions.

BORDER CARNATIONS.

IT would be hard to picture an English garden which had no spot therein devoted to the culture of the Carnation. By the merit of many virtues this plant has held the esteem of horticulturists from the time when flowers first began their refining influence on mankind till the present day. Nor has it ever suffered eclipse of popularity through spells of neglect, as have so many of the so-called florists' flowers during the last hundred years. And now, in these convulsed, tumultuous times, when many minds dare hardly think of gardens and the sweets of leisure, there is but little sign of any falling off in the demand for good Carnations. I have claimed the merit of many attractive features in the cultivation of these flowers, and when one scans the varied uses to which they can be put; the interest to be extracted from the process of raising, flowering and propagating them; the prevailing good nature and hardihood of the plants and the small amount of trouble involved in bringing them to a successful flowering stage; and the extraordinary range of colour and beautiful shape of the flowers themselves, it is small wonder that the Rose only can compete with them in popular acclaim.

But to get to matters practical, for these notes are, above all, to be a reliable and practical help to Carnation culture for all readers who desire such, and I shall be glad at all times to answer queries and give what help I can to any who care to ask for it.

As regards culture outdoors, there is not a great deal to do at the moment, provided the work is up to date. Beds should have been prepared and planted before now; but if this

BULGARIAN GIRLS GATHERING ROSES NEAR SHIPKA.

Our Arrival at Stara-Zagora.—The fame of our small party of plant-collectors, who had been so favourably received by King Ferdinand, preceded us, and on our arrival at Stara-Zagora we were met by the Bishop and other dignitaries of that town and driven off in phaetons drawn by ill-fed ponies. Cleanliness and godliness are not inseparably associated by the priests of Bulgaria, an article in the popular creed being indeed the sinfulness of washing and hair cutting, conditions which detract somewhat from the heroic ideals with which the bearded priests and monks of Bulgaria are invested in the popular mind. The Bulgarians appear to have little idea of road making, even in the towns, and our queer-looking procession of carriages rattled through the streets until we reached the Bishop's house. Here we were welcomed in accordance with a curious and simple Bulgarian custom known as "drinkee."

Glasses of water and small dishes of over-sweetened jam, made from the fruits of the Cornelian Cherry and petals of the Madonna Lily, are brought in, and each visitor helps himself to a spoonful of jam and as much water as he desires.

vigorously shake hands with us. They would make all manner of utterances in a Slavonic tongue that was strange to us, and then express surprise among themselves that we could not understand them. They usually enquired, so I am told, after the health of one's family, not forgetting uncles, aunts, cousins and far distant relations.

Crossing the Shipka Pass.—High up on the Shipka Pass a general view of the valley of Roses of Kazanlik is obtained, and in the foreground the Russian monastery at Shipka, with its gilded cupolas, stands out in bold relief. This magnificent building was erected by the Russians to commemorate the defeat of the Turks at Shipka Pass. The Bulgarians allowed the Russians to build this noble edifice, and then forbade the inhabitants to use it. We attended Divine Service here, and with the exception of our small party, the priest and a woman caretaker were the only other persons present.

The flora of this district proved most interesting, and among the plants we came across were the Fishbone Thistle (*Cnicus Casabonae*), Honey Balm (*Melittis Melissophyllum*, *Aquilegia lutea*, *Geum coccineum*, *Geranium macrorrhizum*,

has not been done, no time should be lost. Both seedlings and layers from old plants are much stronger and better fitted to stand winter strains by being planted early enough to form strong new roots before frost and cold rains chill the soil below a temperature of 45°. If any of the layers are tall and inclined to "legginess," they must have some support from the buffeting of wind. Seedlings generally are stouter and dwarfer, and can look after themselves in the winter, unless, indeed, the birds show a particular interest in one's stock and make frequent banquets off them. In that case, an occasional dusting with dry and weather-exposed soot will make the leaves less palatable, while at the same time it tends to check soil vermin and also acts as a valuable manure.

If only a small collection is grown, an effectual protection against avian ravages can be secured by stretching cotton over the plants. Layers in pots for culture under glass will winter well in cold frames, and will root very strongly if the pots are plunged in ashes. This keeps the soil equably moist, and secure against extremes of temperature. Abundant light and ventilation must be given at all times, even in hard weather. Carnations have no bronchial tubes and no terrors for low readings of the thermometer, and it cannot be too often emphasised that coddling of hardy plants is mere idle mischief. Water should be given with care and temperance, as a wet, spongy rooting medium is quite against the natural desires of the Carnation, especially during the months of slow growth.

It is not too early to think of laying in a stock of fibrous loam for potting purposes, as this must be at least partially rotted when used. It is, however, a great boon to growers that Mr. James Douglas of Great Bookham is now in a position to supply ready mixed potting soil to customers at a very moderate charge, for potting soil from Edenside is a vastly different product from the all-utility mixtures sold by local dealers. My next article will deal with collections of border Carnations, both as to novelties and the older, proved sorts.

J. L. GIBSON.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Cattleya Luegeæ Fowler's Variety (*C. aurea* × *C. Enid*).—A remarkably handsome hybrid with broad, somewhat undulated, crescent-outlined sepals of a rosy red, and petals of the same rich colouring. The elaborated lip has a heavily crested or plumose margin, the whole of crimson purple hue, and golden, freely reticulated ground near the throat. From Mr. J. Gurney Fowler, Pembury, Kent. **Cattleya labiata alba** Princess of Wales, which had already received a first-class certificate, was shown beside the above.

Scelopendrium vulgare crispum speciosum.—A magnificent example, having a spread of fronds 3 feet or more across, and with fronds nearly 2½ feet in length, was shown of this noble variety, in all probability the handsomest of its class. The handsome, glossy fronds, with pronouncedly goffered or ruffled margins, render it as beautiful as it is imposing. From Mr. W. B. Cranfield, Enfield Chase.

AWARDS OF MERIT.

Cattleya Moira rubra (*C. Fabia* × *C. Martinii*).—The sepals and petals are rich reddish purple, the lip of rich purple hue. It is one of the richest coloured we have seen. From Messrs. Hassall and Co., Southgate, N.

Chrysanthemum Charlotte E. Soyer.—A large exhibition variety of the Japanese section, and coloured yellow. Shown by Mr. Martin S. Silsbury, Shanklin, Isle of Wight.

Chrysanthemum Bertha Fairs.—A big exhibition single with two or three rows of florets. It is of terra-cotta shade and very showy.

Chrysanthemum Market Bronze.—A decorative sort coloured gold and bronze, and with many of the good attributes of a market flower, *i.e.*, short peduncle or neck, and firm, crisp florets indicative of good keeping qualities. These were from Mr. Norman Davis, Framfield, Sussex.

Chrysanthemum General Smith-Dorrien.—An exhibition variety of maroon crimson, and gold reverse.

Carnation Aviator.—Not quite a novelty, though, as shown, one of the richest scarlets we have seen. From Messrs. W. Wells, Limited, Merstham.

The whole of the foregoing novelties were before the Royal Horticultural Society on October 26, when the awards were made.

ALLIUM KANSUENSE.

This species has received very favourable mention lately in some deeply interesting accounts of a search for new plants. I am not surprised at the admiration it has excited, as it is a really charming little bulb, excellent for the rock garden. It was offered in catalogues a good many years ago, and I had the pleasure of growing it for some little time. I believe, however, that I lost it during a prolonged winter of almost Arctic severity which occurred some twenty or so years ago. It is a dainty little plant, with steel blue flowers, and is, or was with me at least, about 6 inches high. I am not sure that it is in the market now, but it probably will be again soon, and will be worth securing by those who like bulbs of this size on their rock gardens.

S. ARNOTT.

ROSE FORTUNE'S YELLOW

(*ROSA CHINENSIS PSEUDO INDICA*.)

BY MISS ELLEN WILLMOTT, V.M.H.

FROM time to time I have noticed references to this Rose in THE GARDEN. Each correspondent has given his own method of cultivation, all of which are stated to have been successful. Many *habitués* of the Royal Horticultural Society's shows will remember the beautiful exhibits of this Rose sent up from Lockinge for

THE RUSSIAN MONASTERY AT SHIPKA PASS ABOVE A FERTILE VALLEY OF ROSES.

BORDER CHRYSANTHEMUMS AT HAMPTON COURT.

so many years by the gardener, Mr. Fyfe. In a note by his successor upon the cultivation of this Rose at Lockinge, regret was expressed that such a fine Rose should not have become more popular during the many years it has been in cultivation in England. I believe that the reason for its scarcity is its extreme capriciousness.

Several friends who have imitated the conditions which prevail at Lockinge, and also at Barkham, have, nevertheless, been unsuccessful. I have tried to grow it in both ways, and have bestowed every care upon it, but with no better result, so I finally made away with the plants. There is, however, a plant here at Warley which will compare with the Lockinge plant for its size, wealth of bloom and fine colour. Many years ago it was put in a corner of the orangery and forgotten. The roots found their way through the box into the ground below. Beyond cutting out the old wood from time to time, the plant has had no attention whatever. I mention this instance to bear out my suggestion that to its capriciousness may be attributed its loss of popularity. It is rarely satisfactory in the open in England; sun is essential to its flowering and also to the ripening of its wood; but when put against a south wall it becomes infested with red spider, thrip, &c.

In my garden at Tresserve in Savoy, this Rose, growing over the *perron*, is one of the glories of the garden. Its wood has a better chance of ripening on the Continent than it has in England. One of your correspondents suggested that it should be called Fortune's Rose or Beauty of Glazenwood, as Fortune's Double Yellow was a misnomer. Although the colour is very varied, yellow is predominant. To call it Fortune's Rose would create confusion, in view of the large-flowered Banksia, which is also Fortune's Rose. Moreover, it is only permissible to change a plant's name when the law of priority is applied.

For those of your readers who are interested in the history of plants, and who may not have seen my account of this surpassingly beautiful Rose in "The Genus Rosa," I add the following particulars: It attracted the attention of the celebrated botanical collector, Robert Fortune, when, in 1842-6, he was travelling in China in search of new plants for the Horticultural Society of London. While at Ningpo he paid frequent visits to the different nurseries, and also to the gardens of the Mandarins, which, although small, were extremely gay, particularly during the early months of the year, and contained a number of new plants of great beauty and interest. In his narrative (Journal of the Horticultural Society, Vol. I., page 218, 1846) he thus describes his first sight of this Rose: "On entering one of the gardens on a fine morning in May, I was struck by a mass of yellow flowers which completely covered a distant part of the wall; the colour was not a common yellow, but had something of buff in it, which gave the flowers a striking and uncommon appearance. I immediately ran up to the place, and to my surprise and delight found that I had discovered a most beautiful new yellow climbing Rose. I have no doubt from what I afterwards learned that this Rose is from the more northern districts of the Chinese Empire, and will prove perfectly hardy in England." He sent plants to Chiswick in 1845. Lindley's description sounds tame after Fortune's glowing account. He says it is a straggling plant with the habit of *Rosa arvensis*, Huds., and that with its loose petals the whole flower has the aspect of a slightly domesticated wilding; but he adds that Mr. Fortune still continues to speak highly of its beauty in China.

Messrs. Standish and Noble of Bagshot endeavoured to dispel the unfavourable opinion of Lindley, attributing the defects of the Rose to unsuccessful culture and injudicious pruning

of the previous year's growth, upon which the flowers are produced. They certainly proved the truth of their remarks by exhibiting splendidly grown specimens, which in June, 1852, were the admiration of all who saw them. Since then Fortune's Yellow has been grown in many parts of the country, both in the open and under glass. It is hardy in most countries, but the inclemency of our climate often injures its blooms. Grown in the orangery at Warley, where it has protection against the vagaries of our English summer, it is greatly admired, not only for the rare beauty of its flowers, but for the graceful wreaths in which it produces them. For many years a beautiful mass of its flowers has been exhibited at the Royal Horticultural Society's shows, sent from the garden of Lady Wantage at Lockinge.

As this Rose is sometimes erroneously called *Rosa fortuniana*, it is as well to explain here that the mistake has arisen from what was probably a clerical error in Paxton's "Flower Garden," Vol. III., page 157*, where, under the heading *Rosa fortuniana*, is quoted the description of Fortune's Yellow Rose which had previously

appeared in the *Botanical Magazine*. The true *Rosa fortuniana* is described in the "Flower Garden," Vol. II., page 71†, and the description is accompanied by a good black-and-white drawing. There is no similarity between Fortune's Yellow and the true *Rosa fortuniana*, which is a large-flowered Banksian Rose, probably a hybrid of *Rosa Banksia*, Ait., and *Rosa lævigata*, Michx.; whereas Fortune's Yellow Rose, according to Crépin, may be a garden form of *Rosa gigantea*, Collett, ex Crép.

A writer in the *Gardeners' Chronicle*, June 3, 1856, describing a visit to the Horticultural Society's garden at Chiswick, says: "As to Fortune's Climbing Yellow China, its rich nankeen colour was actually glowing with salmon, the house was piled with gigantic Roses, sweeter than the sweetest of the Eastern world."

NOTES ON BORDER CHRYSANTHEMUMS.

THESE are useful in the garden for several purposes, namely, as plants for furnishing the borders during the latter part of the summer and the early part of the autumn; for lifting at a certain stage of growth, potting and placing in the greenhouse, conservatory, or glass porch to provide a prolonged display of flowers there; and also for supplying cut flowers for vases. They are extremely serviceable for amateur cultivators, especially in town and suburban gardens, as they can be grown from the

* 1852-3. Bull. Soc. Bot. Belg., Vol. XXVII., page 150 (1888).

† 1851-2. Bull. Soc. Bot. Belg., Vol. XXVIII., Part II., page 11 (1889).

cutting to the flowering stage without the aid of artificial heat or even the use of frames. Early flowering varieties are being used with great success in the flower garden in place of certain kinds of summer bedding-out subjects. In recent years many splendid varieties have been raised of dwarf habit, bearing flowers of much substance, rich colours, some very distinct. Nearly all can be grown naturally and without the need for much staking.

Now we have such results as seen in the illustration on page 544 of the varieties Aquitaine and Normandie, the former salmon bronze on an ochre ground, the latter a delicate pink. Aquitaine possesses large, drooping petals, building up a deep bloom, and Normandie produces very compact flowers. The height of both is between 2 feet and 3 feet, with branching habit. There are many excellent varieties now available, and cultivators are not able to resist the majority of them; but by far the best effect is obtained by growing fewer varieties and more plants of each.

Twelve Additional Varieties.—The following are a dozen varieties of great merit and easily grown: Caledonia, ivory white, 2 feet; Mme. Marie Massé, lilac mauve, 2 feet; Autumn Beauty, bronzy yellow, 2 feet; Cecil Wells, buttercup yellow, 2½ feet; Dolly Reeves, deep pink, 2½ feet; Gertie, salmon pink, 18 inches; Horace Martin, yellow, 2 feet; La Somme, deep mauve pink, 2½ feet; Le Pactole, bronzy yellow, 3 feet; Pink Pearl, deep pink, 2 feet; Mrs. W. Sydenham, deep crimson, 2 feet; and Champagne, rich ruby red, 2½ feet.

Positions and Soil.—An open quarter with a low shelter at a short distance away on the north and east sides is the best, but really good results follow when plants are grown in partially sheltered places, such as under the shade of high walls and trees. Clayey, gravelly and sandy as well as good loamy soils will do if they are deeply dug or trenched, and it is an easy matter to feed the growing plants. *AVON.*

CHRYSANTHEMUM ARCTICUM.

IN the month of October flowers in the rock garden are scarce, so that a plant which makes a display at this time is doubly welcome. In *Chrysanthemum arcticum* we have a dwarf-growing perennial Daisy of neat, compact habit, coming into bloom at the beginning of the month and producing a succession of large white flowers till the frost comes. It is a native of Lapland and Arctic Russia, and while, botanically, closely allied to our native Ox-eye Daisy (*C. Leucanthemum*), it differs in having erect, branching stems of a more shrubby appearance. Growing less than 12 inches high, the stems are well furnished with dark green, rounded leaves, while the white flowers are 2½ inches in diameter.

It is an easy plant to grow in a cool, partially shaded position, planted in moist, gritty loam. Owing to its late flowering period, seeds are seldom matured, but propagation may be effected by means of division in the spring. *W. I.*

NERINES, OR GUERNSEY LILIES.

BY THE REV. JOSEPH JACOB.

ARE Guernsey Lilies coming into favour? To see their flowers on a sunny day at the end of September or in October in their full beauty, looking as if they were powdered with diamond dust or made of exquisite tinsel, is to see an exceedingly lovely sight. Even without any sun they are very beautiful. The many flowered pink, rose, orange red or rich crimson umbels, daintily poised on the long, slender stems, cannot fail to attract all but the blind. Small wonder, then, that as a very prettily arranged display by Messrs. Barr and Sons of Covent Garden was one of the first things to be seen on entering the Royal Horticultural Society's Hall on a certain Tuesday in October, everyone "made" for them, and in many cases notebooks were brought out and names taken down, which is the equivalent of saying, "I like you; I must have you if I can."

This particular display was especially attractive, as Mr. Mudge had introduced a few pots of various pale-hued autumn Crocuses in front of the bright Lilies, and the effect was fine. Why does not everyone grow them? What flower can touch them in October for brightness? How is it that, after being in French and British gardens for two hundred and fifty years, it is still very much a *rara avis*? I am sorry to say there is a good reason why it has been so in the past. The true Guernsey Lily is a shy bloomer, and its behaviour in this respect has worried successive generations of florists ever since John Morin grew it in Paris and de St. Marets (de Saumarez) in Guernsey, and no coaxing or threatening has improved it.

CHRYSANTHEMUM ARCTICUM, NATIVE OF LAPLAND AND ARCTIC RUSSIA, NOW FLOWERING AT KEW.

Rapin, a French Jesuit, in the latter half of the seventeenth century, wrote:

"This flower, ye skilful Florists, often plant,
Let not our nation this fair beauty want;
And tho' she answers not your common care,
No cost nor labour on her dressing spare,
For should she but her conquering charms display,
From every fair she bears the prize away."
—Gardiner's translation.

This still remains strictly true of the old original *Nerine sarniensis*, the exquisite, broad-petalled, soft rose coloured flower that has given its popular name to the family. It is awfully shy, and anyone who will get one in three to bloom deserves a cultural commendation.

But better times are coming. Thanks to several hybridists and raisers of seedlings, new blood has been introduced, and we have now a race which is far more amenable to good and proper cultivation. There are varieties, such as *corusca*, *Fothergillii* major, *Lady Bromley*, *Epic*, *Lady de Walden*, *Mrs. Harrison* and others, which give us flowers practically every year if given the right treatment. Surely there must be some enthusiasts to whom difficulties to be overcome are but the breath of life. Here, then, is your opportunity — take up *Nerines*. They ask for a cool greenhouse in which to bloom and grow, a perfectly dry, sunny spot in which to æstivate, and a good rich, porous loam on which to feed. Messrs. Barr and Sons have been fortunate in securing many gems from the famous collection of Mr. H. J. Elwes, and these, with some additions from Guernsey and elsewhere, made up the fine collection which I have spoken of before. I noticed the following: *Lady Clementina Mitford* (pink), *Duchess of Normandy* (salmony rose), *Vivid* (rich scarlet), *Epic* (deep rose), *Mrs. Douglas* (pale rose), *Venus* (soft pink), *Rotherside* (beautiful

coral), Miss Ciceley Elwes (crimson and purple), Radiance (a deep rich cerise), Mrs. H. J. Elwes (pink), Lady Lawrence (salmon), Duchess (silvery pink and lavender), Garibaldi (magnificent cerise), Lady Bromley (deep rose and pale purple), and Lady Mary Shelley (charming soft-toned pink).

AUTUMN FLOWERS.

By E. A. BOWLES, M.A., F.L.S.

THIS year St. Luke has taken charge of the weather rather earlier than the date of his day in the calendar might warrant. His kindly interference is so thoroughly welcome, both to me and my Crocuses, that the longer St. Luke's Summer lasts the better we shall be pleased. It seems to me that never before

Horticultural Society's meeting; and my favourite of all, a nearly white or pale French grey seedling I had the good fortune to find in my seed-beds here one sunshiny morning five years ago. It has retained a trace of the lilac veinings on its inner segments, and when open in the sunshine is a very remarkable flower.

C. caspius is very good this year, and its rich orange throat makes it stand out, even from a distance, as one of the best white kinds. *C. medius* is better than usual, I think, and extra large. A colony under the light shade of the Vine pergola was singularly beautiful this morning when the mauve flowers were half expanded, and looked as though a flame burnt inside each cup, the effect of the wonderfully deep scarlet of the stigmata. *C. asturicus*, in pale and deep shades of lavender; *Salzmännii*'s rather flimsy but pearly lilac flowers; *cancellatus* in every imaginable shade between pure white, lilac and amethyst

narrower in all its parts than any other *Crocus* designer could have dared to devise without making a poor, thin flower. In this case the hair-like leaves and starry blossoms are very distinct and pleasing.

The mention of starry blossoms reminds me that *Narcissus serotinus* is now in bloom, and as it is leafless at flowering-time, I am trying the effect of planting it among some patches of *Dianthus neglectus*. It looks very happily placed now that it is in flower, and I hope its long leaves in spring will not annoy the Pinks. *Galanthus Olgae* is this year the first of the autumn Snowdrops, and is just at its best in a border I cleared of summer flowers and weeds about a month ago. Evidently the rains reached its roots better there than in the rock garden, for there not a nose has appeared as yet where my largest colony should be. A canful of water poured out as a libation a day or two ago will, I hope, soon bring it to the surface. Four blooms of *Iris unguicularis* have appeared up to the present, and *Caryopteris Mastacanthus* is in full bloom. So long may St. Luke's Summer and its precious flowers last!

TWO HARDY CÆSALPINIAS

WHEN writing of hardy *Cæsalpinias* one can only do so with a feeling of reservation, for they are only hardy in certain parts of the British Isles, and even then they must be given

favourable positions if really satisfactory results are desired. But they are so attractive, both in leaf and flower, that we may well put ourselves to a little trouble in order that they may have the best possible chance of success. They are essentially sun-loving plants and should be fully exposed to the south or south-west, with shelter from the north and east. Rather light and well-drained loamy soil should be provided, and it is advisable to place young plants out of doors in spring in order that they may become well established during the summer months. The best known species is *C. japonica*, a loose-growing Chinese and Japanese shrub with dark red branches armed with stout thorns and bearing large, handsome, bipinnate leaves made up of a large number of small leaflets. The flowers are borne in racemes, 6 inches to 12 inches long, in June and July, thirty to forty blossoms often occurring in each raceme. The petals are yellow and the long thread-like stamens bright red. It may be grown on a sunny bank or against a fence or wall in the Southern Counties, and can be increased by root cuttings in spring.

The other species is *C. Gilliesii*, a native of the Argentine Republic. It grows into a small tree in its native country, but must be planted against a wall here. The doubly pinnate leaves are divided into a large number of dainty leaflets, which are attractive throughout the summer; while the erect, terminal inflorescences, often 9 inches to 12 inches long, are lovely in August. The petals are large and rich yellow, while the thread-like stamens, each 2 inches to 3 inches long, are bright red. It stands uninjured against a wall through ordinary winters, but may be injured by severe frost. Propagation is usually by imported seeds. To give the plant a proper chance of success, it should be placed against a high wall where it will not need to be pruned severely.

W. D.

CÆSALPINIA GILLIESII, A LITTLE-KNOWN WALL SHRUB WITH YELLOW FLOWERS.

in my experience have the early and late autumn Crocuses managed to flower so simultaneously. As a rule, *C. zonatus* is almost a thing of the past by the time *pulchellus* and *lævigatus* put in an appearance. All three, however, are now at their best and revelling in the still sunny mornings. *C. speciosus* is making drifts of blue in most of the flower borders, and is fast invading many banks of the rock garden, and with its pure white form, its large pale variety *Aitchisonii*, the varied blues and lilacs of the type, and a specially bright blue one I have long grown as var. *globosus*, produces a charming amount of variation. The forms that please me most are the large, pale but richly veined variety Mr. Van Tubergen calls the *Artabir* variety; the hybrid between *speciosus* and *pulchellus* that, sooner or later, is sure to appear wherever those two species are grown side by side in any quantity, and which Messrs. Barr showed very well at a recent Royal

purple, and most of them richly feathered; the yellow and white *ochroleucus*; and *Clusii* in many shades of lilac, were all widely open. *C. nudiflorus*, so plentiful in the Pyrenees and round Biarritz, and so easily grown, yet so seldom seen, is one of the richest in colour of all, a warm bright purple. *C. Tournefortii* in pearly tints of lavender is exquisite, especially if under the shelter of some overhanging bush, for its flowers, once open, never close again, even at night. *Hadriaticus*, either pure white or with yellow and bronze markings at the throat, is a good white one, and not too particular as to its treatment. Some seedlings of *sativus Pallasii* come very near it in form and colouring. I used to think the *sativus* forms lacked yellow in the throat, and *hadriaticus* nearly always possessed some; but the seed-beds have taught me that this idea must be given up. *C. olbanus* is a queer creature, and looks like some *sativus* variety designed by Chippendale and made longer and

TWO 1916 DAFFODIL SCHEDULES.

THE appearance of the Royal Horticultural Society's and the Midland Daffodil Society's schedules is always an event of some importance to all who show Daffodils. To compare small things with great, they are perused by many Daffodilers with just as keen an interest as the daily papers were on the morning of September 23, 1915, by the British taxpayer, who was anxious to know what the new Chancellor's War Budget was like and how it affected him personally. So it is with the advent of these two leading schedules. The man who exhibits turns to them to see what is in store for him next year, for to a very large extent these are the bell-wethers of Daffodil showdom. They are scanned just as keenly in Australia and New Zealand as they are at home; and their influence is great.

This year, as the result of resolutions passed last spring by the Daffodil committee of the Royal Horticultural Society, two very important changes have been made. First, the Leedsii class has been divided, so that we now get the old type, of which Duchess of Westminster and Mrs. Langtry may be cited as typical blooms, put into one division; and the newer large-cupped varieties, like White Queen, placed in another. The determining factor is the relative length of the perianth segments, compared with the depth of the cup. What in the case of the yellow cups makes an incomparabilis, here makes a Giant Leedsii; and what makes a Barrii, here makes a Leedsii.

The change is one for the better, and I feel sure it will be very generally followed, as year by year the giants are becoming more and more numerous. The second innovation is the introduction of what may be conveniently called "Bantam" classes. For a long time it has been patent to all observers that the show tiers were no place for small flowers, however refined and beautiful they might be. Everything there had to be of the six-foot Guards type. Now, coinciding with the appearance of the Bigland Bantams, provision is made for the small 3 inch and under Daffodils. Why should not they have their opportunity? [This is a welcome change that should have been made years ago.—ED.]

A Bantam may be as useful a soldier as a Guard, and a little woman may be every bit as pretty and taking as one of greater height and more ample proportions; so a small bloom may have every requisite that makes for high quality, and yet, just because it has not the doubtful point of size, it has up to the present more often than not been strangled at its birth, or, if allowed to live, it has been

"born to blush unseen,

And waste its sweetness on the desert air."

Now, however, there is a chance for the Wendys and the Pure Golds. Moreover, many a delightful seedling will now be saved and cared for, and brought to the exhibition; and in due time our lists and our homes will be enriched with these gems of beauty and refinement. I am exceedingly glad that the small flower is to be encouraged; it is, according to my view, only what should be, and I have for a long time advocated something of the sort. It has been decided that admission to these new bantam classes should be confined to blooms the diameter of whose perianth does not exceed 3 inches. Time will show if the schedule

makers have hit upon the right qualification. If they have not, unlike the laws of the Medes and Persians, it can be altered.

In judging these classes at London and Birmingham, I sincerely hope "my Lords" will no longer attach any importance to size; in fact, I would suggest that what holds good in Pompon and Show Single Dahlia classes, where bigness is a positive detriment, should equally hold good in these. Here, at any rate, let it not be said: Colour, Balance and Size, these three; but the greatest of these is Size. J. J.

DAHLIAS.

IN this year of stress I have used a large number of Dahlias in borders and beds. It is true they are rather coarse in habit compared with the vast mass of material which we have been accustomed to; but apart from that they are undoubtedly effective to a great degree, and as we are likely to be more handicapped next year than this for necessary labour, it would be worth while to consider the value of Dahlias as a means of saving labour.

Nearly all the Dahlias grown here are treated as tuberous plants, such as Potatoes and Artichokes, and are merely broken up by pulling the roots in pieces when the buds are beginning to push and immediately planted, setting the pieces so that the buds are 3 inches or 4 inches below the surface. That system in itself saves an immense amount

of labour. It is asked, What about frost? Planted in April, the tops do not appear till frosts are usually past, and, strange as it may appear, I do not find these hardily grown plants in spring so susceptible to cold as Dahlias are on the approach of cold in autumn. Then, it is obvious that a plant that will cover a space of from 3 feet to 6 feet square must effect an enormous saving of labour over plants that would entail the

preparation and planting at 9 inches to 12 inches apart.

It may be asked, How about the labour involved in staking and tying? Neither is essential for decorative purposes; rather are they to be deprecated. When the Dahlia shoots, three or four to each plant, are a foot long, all that is needed for the season is to fasten the points close to the ground by means

CÆSALPINIA JAPONICA, A HANDSOME SHRUB FOR A SUNNY BORDER.

of strong hooked sticks, or pieces of Snowberry bent to form a peg, which is a simpler method. As the time for lifting the tubers is again drawing near, I may be permitted to add that they are best preserved through the winter by allowing as much soil to adhere to the tubers as possible. There is no preservative equal to soil, and its removal only renders the safe keeping of the tubers a risk. Dryness and a temperature of about 45° to 50° are also advantageous. R. P. B.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Pot Vines.—To obtain ripe Grapes at the end of April or early in May, the Vines must now be placed in the forcing-house. A lean-to house facing south is most suitable for the early forcing of Grapes, and the house should be well provided with hot-water pipes. The pots should be plunged in a moderately warm hot-bed to help root action. No fire-heat should be necessary for the first two or three weeks; even then only sufficient should be allowed to keep the temperature up to 50°. This may be increased as the growth of the Vines advances. Spray the rods twice daily when the weather is fine, using lukewarm rain-water.

Early Permanent Vines.—If early Grapes are to be obtained from permanent Vines, the house must be closed at once, providing the wood is perfectly ripe. The general treatment of the Vines during the first few weeks may be similar to that recommended for pot Vines. The rods should not be secured permanently to the trellis till the buds are on the point of bursting into growth. At this stage the rods should be given their final scrubbing.

Pot Fruit Trees.—These must now be placed in their winter quarters, except those which will be required for early forcing. These may remain outdoors till the time arrives to start them into growth. In the event of a continued spell of wet weather, they should be placed in a cool, airy house. The main batch of trees may be plunged in leaves or Bracken at the foot of a wall facing south. Here they will be somewhat sheltered from heavy rains. Pot Fig trees must be placed in a cool house, where they will be safe from frost.

Plants Under Glass.

Fuchsias.—The cuttings which were inserted in August or September will now need a shift into larger pots. Pot fairly firmly in a light, rich compost, and keep them growing steadily in a temperature of 50° or 55°. Keep them near to the light and afford them plenty of room. Old plants may be gradually induced to rest by giving them less water at the roots. In a week or two they may be laid on their sides beneath a stage in a cool house.

Violets.—Decayed leaves must be removed regularly, or damage to the flowers will result. Afford the plants abundance of fresh air, and during favourable weather remove the lights altogether. When water is needed, apply it, if possible, on a fine morning, so that the foliage will get quite dry by night.

The Flower Garden.

Lily of the Valley.—This needs lifting and replanting every two or three years. To ensure a good supply of flowers annually, only half the bed should be dealt with at one time. The ground must be deeply dug and well manured, taking care that it is well cleaned in the process. Select the strongest crowns for planting, which must be done in rows about 9 inches apart.

Planting Roses.—The making of new Rose beds or replanting old ones should be done, if possible, before the turn of the year. The ground should be trenched and plenty of well-rotted farmyard manure mixed in with it. Lift the plants with care, lay the roots in the ground on a sheltered border till the beds are ready for planting, and plant firmly. Standards will need the support of strong stakes as soon as they are planted. In planting climbing Roses against a wall or fence, make a hole large enough to take a barrow-load of soil. Newly planted Roses must be well protected during times of severe frost.

The Rock Garden.—The work in the rock garden at the present time consists chiefly in keeping the plants clear of dead foliage and leaves, or many of the choice plants will be damaged. When planting bulbs, take the opportunity to cover the roots of plants which have become exposed. Slugs and snails will be plentiful, and must be diligently sought after.

The Hardy Fruit Garden.

Morello Cherries.—The trees may now be pruned and trained. The fruits of the Morello Cherry are borne on the previous season's growth; therefore just sufficient of this must be left to tie in. Old trees should first be carefully examined, and any old branches that are becoming bare at the base must be cut out, thus leaving more room for the young wood. Before commencing to train the trees, any cleaning which may be necessary should be done.

Strawberries.—Plants which have been put out this season must have all runners removed. When the ground is dry enough, dust soot between the plants, then carefully disturb the soil with the hoe. A mulch of decomposed farmyard manure will be of considerable benefit.

The Kitchen Garden.

Tomatoes.—Plants in fruit must be well supplied with stimulants. Place a little fresh material on the surface of the pots to encourage fresh roots. To expose the fruits better to the light, remove a portion of the foliage. Maintain a temperature of 60°, and at the same time admit air to the house, more or less according to outside conditions. A sowing may now be made for the earliest supplies next year.

Potatoes.—The method of growing the first crop of Potatoes in pots is an excellent one, as they may be grown quite easily in fruit-houses before the fruit trees are too far advanced. For this purpose the tubers must now be selected and placed singly in boxes to sprout. The time of planting will, of course, be governed by the date it is desirable to have new tubers ready for use.

Globe Artichokes.—All dead foliage must now be removed from the plants, and, as a protection against frost, a quantity of ashes must be placed round the base of the plants. In some districts it will be necessary to cover them with Bracken or litter when frost is very severe.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Plants Under Glass.

Shading.—All blinds and shading should now be taken from the roofs of glass houses, if this has not already been done. Where the shading has been put on in liquid form with a brush or syringe, this will be a good opportunity for washing the entire roofs of plant houses, as dirt and soot adhering to the glass prevent the full amount of light reaching the plants during winter. Especially is this the case in and around large towns. The plants most likely to suffer in this respect are Orchids and other flowering plants.

Freeseas are now growing stronger and require staking as the growths lengthen. They resent being forced, and this should not be attempted until the flower-buds are visible. A cool, well-ventilated house suits them best, so that where a special pit is not available, a shelf near the glass in a Tree Carnation or Malmaison house will do nicely.

Bulbs.—Roman Hyacinths and other early bulbs may be introduced to heat as soon as it is evident they are sufficiently rooted. It prevents disappointment to delay starting them for a few days or even weeks, rather than to be in too great a hurry and then have failure, which is inevitable when the bulbs are not ready for forcing. To increase the length of Roman Hyacinth stems, place a good layer of moss over the growths after bringing the plants indoors.

Zonal Pelargoniums.—Where plants have been grown for winter flowering, there is now a good display, as they are very free flowering plants. The most important point in their successful culture through the winter is careful watering, as they prefer to be kept drier than some subjects. A temperature of from 50° to 55° should be maintained at night, allowing it to rise slightly during the day.

The Kitchen Garden.

Tomatoes.—As room is generally scarce indoors at this season, any plants which are nearly exhausted can be stripped of what fruit may yet remain. The green fruit, if put on a warm, sunny shelf in some glass house, will ripen sufficiently to be fit for use in the kitchen. The young plants intended for early fruiting should be grown as sturdily as possible by keeping them fairly cool and near the glass.

Rhubarb.—When there has been sufficient frost, the roots can be lifted and forced. The usual and most easy method is to place them in a Mushroom-house. Where this is not practicable, they can be put near the pipes under stages, or a special hot-bed be made up for them.

Chicory.—As the leaves die down, a few roots can be lifted, either boxed or potted up, and put in the dark, where the leaves will be produced in a blanched condition. A simple way is to pot five crowns in a 10-inch pot, and cover with an inverted pot of the same size. If put in brisk heat, the Chicory will be ready for use in a fortnight to three weeks.

Fruit Under Glass.

Early Peach-House.—The trees in this house will now have dropped all their foliage, so that the house should now be prepared for starting in December. The ties should all be undone, and the branches slung from the wires in bundles so that the washing of the glass and woodwork can be done more easily. A strong mixture of soft soap and hot water should be used for the scrubbing. This over, the trees should be dressed with some insecticide, such as Gishurst Compound. If disbudding has been properly attended to during the growing season, little or no pruning will be required, except removing bare pieces of branches where they can be replaced by younger wood. When the branches have been tied up in their places, the borders must receive a liberal top-dressing. First scrape off all loose soil; then, without damaging any of the surface roots, lightly fork it over. The soil used for top-dressing should be good fibrous loam, enriched with a good lasting artificial manure. It is also very important to add a quantity of lime; this is most essential for stone fruit.

The Hardy Fruit Garden.

Fruit-Room.—For some time after Apples are gathered, there is generally an amount of sweat or moisture given off. This should be allowed to escape freely from the fruit by ample ventilation. When it is seen that this has taken place and the fruit is again quite dry, the ventilators should not be too freely used, so long as the atmosphere is maintained wholesome, otherwise the Apples would shrivel. Pears, however, keep much better in a dry atmosphere.

The Flower Garden.

Planting Shrubs.—Deciduous shrubs can now be planted with safety. The evergreens in most cases, however, are better left until spring, especially in the cases of Yew and Holly. After planting, the importance of protecting against damage by wind should not be forgotten.

Chrysanthemums.—Unless the weather should be very severe, the plants can remain where they are for some time yet. As, however, the varieties are not easily distinguished by their foliage, it should be seen that they are correctly labelled while yet in flower, to prevent mistakes when lifting the stock which is to be retained for producing cuttings.

Herbaceous Border.—With the exception of some late Michaelmas Daisies, this part of the garden is now presenting a bare and untidy appearance where the plants have finished flowering. The majority of the plants are ready for cutting over. This means also the removal of all stakes, which should be tied up in bundles in their respective sizes, so that they may be put tidily in the store for the winter.

Lawns to be kept looking trim and tidy at this season require frequent rolling and brushing, as leaves and worms keep them in a constant state of untidiness.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

A GOOD CULINARY APPLE.

IN the cultivation of Apples, and particularly those varieties that are to be used for cooking purposes, one of the greatest difficulties that besets the inexperienced is the selection of varieties. So many sorts of Apples are now obtainable, and each is set forth in the nurseryman's catalogue as being well worth growing, that the novice may be excused for planting trees of sorts that are, to say the best about them, of second quality. Bramley's Seedling is undoubtedly the best of its kind for culinary purposes, and one that may be planted freely both for private use and market purposes.

In common with many other good things, it was a long time before fruit-growers could be persuaded that in Bramley's Seedling they had an Apple which is superior to any other of its class, and one that would fill the same high position in the culinary section as Cox's Orange Pippin does in the dessert varieties. During the last decade, however, up-to-date growers have realised its possibilities, and so great has been the demand for young trees that nurserymen have found it exceedingly difficult to propagate it fast enough. We know of several nurseries where, owing to the enormous demand, young trees of other varieties which have not sold so well have been cut down and the stocks regrafted with Bramley's Seedling.

The history of this Apple is, fortunately, very well known. In common with a number of other good fruits, it does not, so far as can be ascertained, owe its existence to the hybridist's skill, but originated as a chance seedling at Southwell in Nottinghamshire. Two pips from an Apple, name unknown, were sown in a pot by a Miss Brailsford of Easthorpe, Southwell. Both grew, but one of the seedlings eventually died. The other flourished and was planted out in the open garden by Miss Brailsford, and in due course developed into a large tree, whence all the trees of Bramley's Seedling now in existence—and there must be millions—have sprung.

The lady in question eventually sold the garden, including the Apple tree, to a Southwell butcher, Mr. Matthew Bramley. By this time the tree had attained a large size and was bearing good crops of fruit. Luckily for present-day fruit-growers, the attention of Mr. H. Merryweather, who has extensive nurseries at Southwell, was drawn to the Apple, and with sound judgment he decided that it was one well worth cultivating. In 1876 he had shown fruits before the Royal Horticultural Society, and received a "highly commended" certificate for them. In 1883 this Apple received a first-class certificate, the highest award that is granted by the society to any new fruit, flower or vegetable.

But, as has already been stated, in spite of this high award growers were sceptical about its possibilities, and only a few who were more far-seeing than the majority planted trees in quantity. That they were justified in doing so has been abundantly proved during recent years, as good

samples of this variety always find a ready market at high prices, in spite of the keen Colonial competition that has to be met. It has a very vigorous constitution, makes a shapely tree, and has large, leathery foliage that is not so susceptible to disease as the softer leaves of many other Apples. Grown in standard or half-standard form it is an ideal orchard Apple, and for garden purposes it does equally as well grafted on the Paradise stock which has a dwarfing effect on the tree and induces it to bear fruit while in a young state. The fruits are in season from the end of September until well into the New Year.

In the nurseries of Messrs. H. Merryweather, Southwell, there is an interesting orchard devoted entirely to Bramley's Seedling. The trees are not planted as thickly as they might or ought to have been, but there are seventy-five trees to three acres of land, and this year the orchard has produced 30 tons of Bramley's Seedling, including all small and big fruits, of which 25 tons are fine saleable fruit of first and second grades. Standard trees of this variety, as grown

APPLE, BRAMLEY'S SEEDLING, A HEAVY CROPPER KEEPING WELL INTO THE NEW YEAR.

in this orchard, are in their prime when between forty and fifty years of age. A much younger Bramley orchard, about three acres in extent, planted nineteen years ago, and consisting of 130 half-standards, has this year produced 20 tons of good saleable apples, and not including fallen and small fruit.

LATE - FLOWERED LILIES.

THE Lily season out of doors extends from the flowering of *Lilium pyrenaicum* (which takes place during the latter part of May) till the early autumn. Then the nights grow too cold for the full development of the later blossoms of those that flower at that time. Some kinds that are, as a rule, at their best much earlier in the season will sometimes put off their flowering till a good deal later. An occasional specimen of *Lilium auratum* will furnish a case in point.

Prominently among the late-flowered Lilies stands *Lilium speciosum*, represented in our gardens by several fine and distinct varieties. Supplies of this Lily reach here both from Holland and Japan. The Dutch-grown bulbs flower two or three weeks earlier than the Japanese, but after a season or two in this country the flowering period of the latter is accelerated.

The best of the Japanese bulbs are very fine and yield a correspondingly grand display of blossoms. In richness of colouring they are unsurpassed, and the white-flowered variety, *Krätzeri*, is by far the most vigorous of those bearing flowers of that tint. The later blossoms will, in the open ground, sometimes yield a display till September is well advanced. Even when the weather conditions are unfavourable for the development of the blossoms in the open ground they will, if cut, taken into the dwelling-house and placed in water, expand nicely. A good sandy loam is very suitable for the requirements of *Lilium speciosum*, but it cannot be regarded as in any way a fastidious Lily, whether grown in

the open ground or in pots. These last named are, if kept cool and allowed to flower at their normal season, very useful for the embellishment of the greenhouse at a time when many summer-blooming occupants of that structure are on the wane. One desirable feature of this Lily is that, when subjected to pot culture, insect pests do not give any trouble, as they do in the case of *Lilium longiflorum*.

A grand late-flowering Lily for the outdoor garden is that largely sent here from Japan under the name of *Lilium tigrinum Fortunei*, or *Fortunei giganteum*. The Japanese bulbs are of immense size, and the growth is correspondingly vigorous. The best examples will often reach a height of as much as 6 feet, the stem being terminated by a large pyramidal-shaped raceme of blossoms. As many as fifty flowers are sometimes borne on one stem. Apart from its later-flowering qualities, this Lily differs from the ordinary form of *L. tigrinum* in the blossoms being paler and the stems, as well as the flower-buds, clothed with a woolly down. The ordinary *Lilium tigrinum*,

with its varieties *Leopoldii* or *splendens* and *flore plena*, are all earlier in flowering than this.

That noble Burmese Lily, *Lilium sulphureum*, frequently flowers so late that the blossoms do not open properly. For this reason it is often grown in pots and treated as a greenhouse plant. Under these conditions the tall, slender shafts, crowded with narrow leaves and terminated by large funnel-shaped blossoms of a rich ochre yellow inside, with a reddish flush on the exterior, are very striking.

Another species, native of the same district, frequently behaves in a similar manner. This is the distinct *Lilium nepalense*, which created such a *furor* when it was first shown in bloom some twenty-seven years ago. The flowers of this are reflexed, somewhat after the manner of a Martagon Lily. The colour is a greenish yellow, with a chocolate purple interior. Unless in particularly favoured districts, these two Burmese species must be regarded more in the light of greenhouse than hardy kinds, a remark which also applies to the now very rare *Lilium neilgherrense*, which is even later in flowering than they.

Lilium longiflorum, or at all events the form known usually as *Wilsonii* or *grandiflorum*, will often push up secondary shoots at this season, which each bear a solitary flower. This habit of blooming a second time was strongly claimed for *Lilium Harrisii* when the bulbs were first sent here from Bermuda, but we heard little about it afterwards. While the Lilies here mentioned are the latest of those that bloom naturally in the open ground, the practice of retarding, so generally followed in the case of some kinds, has upset the seasons altogether. By this means blooms of *L. longiflorum* and *L. speciosum*, and, to a lesser extent, others, may be had all the year round. H. P.

POTATO DISEASE.

It has been demonstrated repeatedly that even with varieties subject to disease, comparatively healthy crops can be obtained if the tubers are lifted as soon as the haulm has died down. Apart from the risk of attack by this disease, tubers left in heavy or water-logged soil are liable to suffer from lack of air, with the result that they rot quickly, either in the soil or subsequently in the clamp. It is essential for good keeping that the tubers should be stored clean and dry, with their vitality unimpaired. In a dry, well-ventilated clamp, disease does not spread rapidly, although dead or diseased tubers generally rot. On the other hand, if the clamp is moist or badly ventilated, spores from diseased tubers may infect healthy ones. All diseased and damaged tubers should be excluded from the clamp. Those least affected could be boiled and fed to pigs. The clamp should be made as narrow as practicable, and should be covered to a depth of about 6 inches with a layer of stout straw, through which air can circulate freely. A thin layer of soil, sufficient to keep the straw in position, should be put on, followed by a thicker covering in November to keep out frost. The crest of the clamp must be freely ventilated. It is advisable to store seed tubers in boxes or small lots, and not to mix them with the "ware." In the event, however, of much disease, a change of seed from a healthy crop should be obtained for planting next season. Those who desire further information on the subject of storing Potatoes should apply for Leaflet 173 ("Potato Growing"), issued by the Board of Agriculture and Fisheries, Whitehall Place, S.W.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

TREES AND SHRUBS.

EUONYMUS NEAR TIFLIS (L. W.).—We are not quite sure, from your description, what the trouble which is affecting your *Euonymus* actually is, though we suspect it is due to scale insects of some kind. For these we think you will find nothing better than spraying with paraffin emulsion whenever they are to be seen, making the paraffin emulsion by dissolving a quarter of a pound of soft soap in boiling water, adding two and a-half pints of paraffin (burning oil), and stirring thoroughly with a handful of twigs for about twenty minutes, until the whole has made a creamy mass from which the paraffin does not separate; then add water to make ten gallons. Spray so as to cover all parts of the plants. There are two other very serious pests of *Euonymus*—the lesser ermine moth and the *Euonymus* mildew. The former feeds in great numbers on the bushes, making webs in which the caterpillars pass the night and wet days. If the webs can be cut out while the caterpillars are at home, this is the best treatment; if not, then spraying with lead arsenate should be resorted to, using the arsenate at the rate of 1 lb. to 15 gallons of water. Failing this, use Paris green at the rate of 1 lb. to 160 gallons of water. The caterpillars are small, and at first dirty white with black spots upon them. The mildew covers the ends of the branches and the young leaves with a white felted mycelium, which disturbs the growth and disfigures the bushes very much. Persistent spraying with Bordeaux mixture or Burgundy mixture is probably the best way to keep this in check, or, failing that, with potassium sulphide at the rate of 1 oz. to 3 gallons of water.

ROSE GARDEN.

PILLAR ROSES FOR EXPOSED SITUATION BY THE SEA (Subscriber).—We advise Conrad F. Meyer, American Pillar, Excelsa, Sander's White, Tausendschön or Minnehaha.

ROSES FOR EXHIBITION (R. E. T.).—Of your list we should recommend the following six: Mrs. R. D. McClure, Mrs. George Norwood, Jonkheer J. L. Mock, Lieutenant Chaure, Mrs. George Shawyer and Lady Barham.

YELLOW ROSE TO REPLACE RAYON D'OR (Miss Rowland).—Undoubtedly Constance will replace Rayon d'Or. It possesses more vigour and is practically the same colour. Three good Pears for October and November are Louise Bonne of Jersey, Marie Louise and Beurre Superfin.

CLIMBING ROSE FOR EAST WALL (H. B. W.).—Tea Rambler would be very showy in early June, but it is not so very hardy. Gerbe Rose is fine as an individual flower, but it is not profuse enough to make a great show. We think one of the best for your purpose would be Miss

Helyett. It is a very beautiful variety, and should be in every garden.

FUNGUS ON AUSTRIAN BRIARS (M. H.).—The Rose is attacked by the Rose rust fungus; *Phragmidium subcorticium*, the stage on the shoot sent being the one usually found in spring. The fungus generally winters on the under surfaces of fallen leaves, where its spores now form dark, almost black, lumps. Much may be done to check the fungus by gathering and burning fallen leaves, and by pruning out the shoots which show the red spring form of the attack, and burning them. In addition to this, spraying the bushes with a rose red solution of potassium permanganate would be a wise measure.

TEA ROSES FOR EXHIBITION IN COOL HOUSE (R. F. C.).—The varieties you name should do very well for a cool house, but you should also add Lady Plymouth and W. R. Smith. We advise you to pot the plants without delay and plunge them outdoors in a shady position well exposed. Protect from severe frost by hoops and mats, or you could place the plants indoors until frost is past. Keep them outdoors all the time otherwise, excepting when showing bud; then put them inside, keeping the house well ventilated and shaded during bright sunshine. If you could arrange some glass lights on a framework just to shelter the plants from rain, it would be a good plan, allowing air all around. Prune in April and plunge the plants in a north aspect until the middle of May, then put them in full sun until the buds show colour. The more natural treatment you can give the better. You would find a small canvas tent an excellent thing to assist retarding after the buds are developed. This would protect your blooms, and at the same time keep the plants cooler than glass.

THE GREENHOUSE.

BRUGMANSIA LEAVES EATEN (A. J. B.).—The *Brugmansia* has been damaged by a bug piercing its foliage while quite young, probably while still in the bud state. Possibly spraying with paraffin emulsion at intervals would check the damage. The Cantaloupe leaves are suffering from something wrong with the atmosphere of the house in which they are growing. It is probably not ventilated sufficiently.

AURICULAS (C. O. B.).—We are glad you appreciate the *Auricula* notes that appear in THE GARDEN, and we are always ready to reply to any query that may arise in the cultivation of these plants. At this season a few plants often throw up a flower-spike, but no anxiety need be felt on that score; as a general rule the plants are robust, and it cannot be prevented. Directly the buds are formed they should be pinched off, leaving the flower-stem to decay naturally. At this period of the year it is advisable to watch such plants. When the stem is yellow, it will readily part from the plant, and then a little powdered charcoal should be sprinkled at the point where the stem was removed. As a rule this will prevent any further decay. The plants will flower again in the spring.

SPECIMEN FOR NAME AND MODE OF PROPAGATION (G. B., Anglesea).—The name of the specimen sent is *Tecoma jasminoides*. It is a native of Australia, whence it was introduced fully a century ago. This *Tecoma* is propagated by cuttings, which are not at all difficult to root if ordinary care and attention is given. The cuttings should be taken in the spring or early summer. They must be formed of the current season's shoots, selected when they have lost their succulent character and become partially woody. A length of 3 inches to 4 inches is very suitable for the cuttings, which should be separated immediately below a joint and the bottom pair of leaves removed, when they are ready for insertion. The pots prepared for their reception should be clean, well drained, and filled with a mixture of loam, peat and silver sand in equal parts, the whole being passed through a sieve with a quarter of an inch mesh. On the top of the soil place a thin layer of clean silver sand. Then dibble the cuttings therein, taking care that the soil is firmly fixed around them. After this give a thorough watering through a fine rose, and place the cuttings in a close propagating-case in a structure somewhat warmer than an ordinary greenhouse. They will, of course, need to be shaded from the sun. If you have no propagating-case available, cover the cuttings with a bell-glass.

TREATMENT OF EUCHARIS BULBS (Hon. Mrs. S.).—We fear that your suggestion to keep the bulbs of *Eucharis* in a dormant state till happier times is not likely to prove successful. Carefully dried off and ripened, they might be kept without deterioration for a while, if you could ensure the "happier times" coming next spring. To thoroughly ripen off evergreen bulbs like the *Eucharis*, it should be done gradually, which you evidently do not contemplate, as you speak of getting flowers from them yet. By the time the blossoms are over, the dull days will be upon us, and they are not favourable for the ripening of vegetation of any kind. We have known dormant bulbs of *Eucharis* to be kept for nearly a year without injury, but the conditions were very different from yours. They were bulbs imported from Brazil, and under the influence of a tropical sun had been ripened to such an extent that by the time they reached this country they were almost as hard as a stone. In this way they passed through a winter without injury. It must, however, be borne in mind that they were kept on a dry shelf in a structure where the thermometer ranged from 50° to 60°. You do not say under what conditions you purpose keeping your bulbs during the winter, but, if without fire-heat, they will, even if dormant, be almost sure to perish.

THE GARDEN.

No. 2295.—VOL. LXXIX.

NOVEMBER 13, 1915.

NOTES OF THE WEEK.

A Late Border Chrysanthemum.—A recent visit to the historic gardens at Hampton Court revealed the fact that whereas most border Chrysanthemums are now over, or at least past their best, Merstham Beauty continues to flower with the greatest freedom. It is a bright single pink, with a white ray around the yellow disc florets. When seen in large, bold masses it is a striking and very effective border plant.

Peach Peregrine.—I have found this a splendid variety for a south wall. Fruits have been produced from our tree weighing from 8oz. to 10½oz. They have a smooth, brilliant crimson skin, the flavour is melting and excellent, and are in season at the end of August. This variety is also suitable for growing under glass.—C. RUSE, *Sulhamstead*.

Sedum spectabile as a Bee Flower.—I am not a keeper of bees, hence I know but little of the ways of these busy insects. That *Sedum spectabile* is particularly attractive to them, as well as to butterflies and others, when it is in flower is well exemplified in my own garden. The heads of bloom are at times crowded with bees, but the result of imbibing the nectar is that many of them get into quite an intoxicated condition, so that they cannot fly for a time; in fact, some of them fall to the ground and perish. I have sometimes wondered if those that fly away with the intention of going home are able to distinguish their own hives, as well-behaved bees should. With regard to the ornamental qualities of this *Sedum* there can be no question. The variety *atropurpureum*, with its richly coloured blossoms, is also worthy of a place in every garden.—H. P.

Escallonia macrantha.—What a glorious shrub this is for seaside planting! In and about Colwyn Bay it is used with good effect for hedges, wall climbers, specimens, and even employed as standards. The deep green of its foliage, combined with the rosy pink blossoms, which are more or less in evidence, form a pleasing contrast, especially as a wall climber. At the "Flagstaff," on the western side of Colwyn, at an elevation of 450 feet

above sea-level, is one of the finest hedges of this shrub I have yet seen. It is fully 80 yards long, 5 feet high, and as much as 15 feet in width, a dense thicket of foliage and blossom.—E. M.

Fruit of *Passiflora edulis*.—This species is a native of Brazil, and it is said to carry heavier crops of fruit than any other Passion Flower. Occasionally it is grown under glass in this country for the sake of its fruits, the pulp of which has an agreeable orange, though acid, flavour. It is not, however, to be compared with a well-ripened *Granadilla* (*P. quadrangularis*), a fruit of which often weighs as much as 3lb. and measures

prior to a new issue of that useful publication. Varieties registered since the issue of 1914 will be included in the new edition. Raisers and distributors are reminded that the registration fee is 2s. 6d. per variety, and those who wish to have their newly named varieties included in the new Classification List should apply at once for registration forms to Mr. C. H. Curtis, hon. secretary, Narcissus Committee, Adelaide Road, Brentford, Middlesex.

Gladiolus masoniorum.—This interesting and distinct *Gladiolus* was first discovered in Tembuland in 1910, and although perhaps not so conspicuous as some of the better-known kinds, it is certainly worth attention. It was sent to the Cambridge Botanic Garden in 1911, where it was grown in pots, and flowered for the first time in 1912. The following year it was tried outside along a border of one of the plant-houses, where it flowered the same year and has done so each year since. At the present time (November 6) it is bearing spikes of soft creamy coloured flowers. It is not likely to prove hardy enough for cultivating in the open, owing to its late flowering, although it has stood 11° of frost in its present position; but a group of this little-known plant, flowering outdoors early in November, is certainly interesting.

A Useful Acacia.—Flowering from now onwards through the winter, *Acacia platyptera*, the Winged

Acacia, is one of the first species to blossom, and is thus a most useful plant. It may be grown in pots for several years, and later is useful to plant in the greenhouse border against a wall, to clothe a pillar, or supported with stakes when the plants attain a height of 6 feet or more. If a fair number of the old flowering growths are cut out each year in spring, the plants can be grown successfully in 6-inch, 7-inch and 8-inch pots for some years. It is a native of the Swan River, and the flowers are golden yellow. *Acacia alata* is a useful companion plant, similar in habit, with pale yellow or sulphur coloured blossoms, freely produced at the present time.

A DISH OF FRUITS OF PASSIFLORA EDULIS.

6 inches or more in diameter. The fruits of *P. edulis* are about the size of a hen's egg and pale bluish in colour. The best-known Passion Flower in this country is undoubtedly *P. caerulea*, often seen outdoors growing over porchways and sunny walls. The orange-coloured fruits are still hanging freely on this hardy species, but they are not edible as far as we are aware.

A Classified List of Daffodil Names.—We are asked to announce that the classification sub-committee of the Royal Horticultural Society's Narcissus and Tulip committee will meet at an early date for the purpose of revising the "Classified List of Daffodil Names"

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Plum Coe's Golden Drop and Pear Pitmaston Duchess.—Your correspondent "E. M.'s" experience with Plum Coe's Golden Drop, issue October 30, page 527, is not mine. Here I have old trees the fruits of which

had the curiosity to scratch down and find the bulb, we have found it plump and healthy, just, in fact, as if it had been set a day or two before. For all the world it might have gone off instantly to sleep the moment it was potted, and forgotten to grow. What happened to these sleepers I was anxious to find out, so certain "gentlemen" were marked down, and last August they were duly planted once again. They are now growing away as strongly as anyone could wish to see.

Their rest has done them good, or they have got tired of doing nothing and have amended their ways. Similar eccentric behaviour is often found in certain members of the Lachenalia family, as, for example, in the true *L. aurea* and some of its immediate offspring. Perhaps some of your readers who are learned in teratology (I hope I have got the right word) will give us an explanation, for doubtless others besides myself who grow Freesias and Lachenalias will be interested to hear the scientific explanation. — JOSEPH JACOB.

Eucalypts for English Gardens.—I have read with interest the recent articles on the Eucalypts, which appeared in your columns. Perhaps my own experience will be of interest. I have often raised Eucalypts from seed, but until recently utilised them as house plants. When they grew too large to handle I threw them away and raised some more. Some time ago, however, I decided to plant out a tree that had outgrown the house, and did so. This tree was some three years old.

At the same time I planted out a yearling. That happened six

years ago. Now, the seven year old tree is 29 feet high and has a trunk about 6 inches in diameter. The older tree is about 15 feet high, with a trunk in proportion. Both are of the same variety and both are planted in a sheltered position with a south aspect. This seems to prove Mr. E. A. Bowles' statement that potted plants make inferior garden specimens. Though both of my trees were potted, the one which was planted in the open when young has done far better than the other. Unfortunately, the gardener mixed the seeds, and I do not know whether the trees are *E. resinifera* or *E. globulus*.

I am sending sprays cut from the larger tree to you for identification. The trees have one peculiarity: at the same time they produce differently shaped leaves. The sickle-shaped leaves are produced on the upper 20 feet or so; the rounded, opposite type nearer the ground. Ordinary staking I have found useless; a tripod of 2 inch by 2 inch beams seems the only satisfactory method of keeping these top-heavy trees in the ground. Here we are 300 feet to 400 feet above sea-level, and are exposed to south-west gales. Our soil is loam on chalk—very little loam and lots of chalk, save where trenches have been dug and filled with purchased soil. The Eucalypts are not in well-trenched soil—perhaps it is 18 inches deep under the stem. Chalk should suit the Eucalyptus, judging both from my experience and from what I have heard from Australians. The trees can absorb an unlimited supply of water, and I have heard of cases where they choked drains with their roots, obtaining access thereto through infinitesimal flaws in the masonry. Chalk holds water like a sponge, and thus should suit the Eucalyptus to perfection.—R. S. D., Sutton, Surrey. [The leaves sent are those of *Eucalyptus globulus*. The blue and more rounded are the immature, and the dark and sickle-shaped ones the final, form assumed by the tree when it reaches flowering age. In view of the great interest now taken in Eucalypts grown in this country, and not with the idea of making an unfavourable comparison, we illustrate on this page a remarkably fine tree of *E. globulus* growing in the Botanic Gardens, Christchurch, New Zealand. —ED.]

EPITAPH ON A GARDEN FRIEND.

THIS patriot, born in peace, in war laid down
His doublet red for vesture earthen brown;
But haply, patriot still, his small soul flies
To perch upon the gate of Paradise,
And greets with music all that come his way
From deck or trench, who loved the Robin's lay.
MARY ADAIR MACDONALD, in *Country Life*.

The Origin of the Loganberry.—I read an article on page 487 of THE GARDEN for October 2 in which it is said of the Loganberry, "Reputedly it is the result of a cross between a Blackberry and a Raspberry, but some are inclined to think that it is a true natural species." The Loganberry was first introduced by and takes its name from Judge Logan somewhere between 1890 and 1895, the result of a cross between a Blackberry and a Raspberry. Judge Logan lived at Santa Cruz, California, and was at the time Judge of the Superior Court there.—R. H. PRICE-DENT, *Hallaton Manor, Market Harborough*.

Crocus Species.—No doubt, as "T. A. W." says, a profitable business must be the chief object of nurserymen; but they also, I feel sure, find pleasure in introducing beautiful plants. We need not compare them with the Dutch Crocus. They bloom at a different time, and their beauty is of a different kind. Those of your readers who have not tried it should grow *C. speciosus*. It sows itself freely and never encroaches. A self-sown colony with about 200 blooms of this lovely Crocus in a Rhododendron bed has been a delight. The soft purple flowers of *C. Sieberi* are charming. One complaint of our friends the nurserymen I do wish to make: How can they offer plants like the *Calystegias*, *Epilobium angustifolium* and *Linaria pallida* without a word of warning!—F. A. STURGE, *Coed Efa, near Wrexham*.

THE BLUE GUM TREE (EUCALYPTUS GLOBULUS) IN NEW ZEALAND.

have such tough skins and hard flesh that, notwithstanding their sweetness and flavour, they are not worth growing. While I am on the subject of fruit, why does anyone grow Pitmaston Duchess Pears except to please the eye? Bottled they are excellent, but otherwise they have all the faults Pears can have, the chief of which are acid flavour and tender skins, which discolour on the slightest provocation.—E. R. M., *Braziers Park, Ipsden, Oxon*.

A "Rest Cure" for Certain Plants.—In past years we have frequently noticed gaps in some of the pots of hybrid Freesias, and as often as we have

A Wild Daisy at the Cape of Good Hope.—I enclose a photograph of *Dimorphotheca pluvialis*, an African Daisy with a fine white flower about $1\frac{1}{2}$ inches across. Like most of the family it only opens after the sun is well up, and closes before sunset. This Daisy flowers in September and grows thickly, as the photograph shows. Seen from a little distance a bank of it resembles a drift of snow.—A. MENNIE, *Cape Town*.

Ononis cenisia.—I should be grateful to any of your readers who would tell me how to grow *Ononis cenisia* so as to prevent its perishing during the winter. I have found it growing luxuriantly on the outskirts of the Pine woods at Lanslebourg, where it must be under snow for many months at a time. All of its companions there that I have brought home are hardy and complaisant enough under cultivation. Among them are *Gentiana cruciata*, *Scutellaria alpina* and *Saponaria ocymoides*, all of them as hardy as a Dandelion, yet this charming little Rest-harrow has never yet survived the winter here, and I know is not too easy to keep alive at Bitton, one of the most successful of all English gardens in growing difficult plants. It is so pretty in October, trailing over grey Kentish-rag rocks, its long sprays freely set with the dainty pink and white blossoms, that I hope someone may suggest a way of preserving the old plants for another season, and so save me the necessity of starting the group again from seedlings.—E. A. BOWLES, *Waltham Cross*.

Nerines.—"Daffodils in the spring, Nerines in the autumn," is a phrase I recollect, used, I think, by Mr. Bennett-Poë when he and I were looking at one of Mr. Elwes' charming lots of Nerines, and I have always looked back on this remark as an excellent "tip" for those who (as I do) work on the Daffodil in the spring. Nerines give Daffodil hybridists something to do in the autumn. A very little glass is required. They can be flowered and seeded even in a quite unheated structure. I know this because Mr. Reuthe tells me that he grows his entire collection in cold frames, and the soil in the pots is frequently frozen hard through in the winter. At the present moment I have a taking little batch of these plants, commercial varieties and seedlings of my own raising, flowering in a house where up to now a little heat is only given at night, just to keep the temperature regular. Almost every day a fresh seedling is opening its first buds, and the interest of these novelties serves to while away the unexciting days of autumn. I am told that several prominent Daffodil men are now taking up the cultivation of the Nerine, including the Rev. Joseph Jacob, and in my dreams I sometimes visualise a Nerine Show, held on the lines of the great Spring Daffodil Show, with classes for seedlings. I wonder if it will ever become an accomplished fact.—ORNATUS.

A Small Garden Turned to Good Account.—The paragraph in THE GARDEN for October 16 about a profitable hospital garden at Exeter

encourages me to send you a short note upon a smaller venture at Cambridge. Last spring our local District Nurses' Home started a small vegetable garden, whose dimensions are only 27 yards by 16 yards. The expenditure upon this plot from March to September amounted to £3 14s. Of this sum £1 3s. was spent on seeds, and £2 2s. represented the wages bill, the sole labour employed being that of a man for occasional work. The produce, of which a careful account has been kept and valued at market prices, is estimated as follows: June, value 16s.; July, £1 10s.; August, £1 10s.; September, 10s.; vegetables in store, £4—total, £8 6s. Considerably over £4 has thus been saved in the course of a few months by this experiment in growing vegetables at home, and a small garden has been turned to good account. Well may the Board of Agriculture remind us that "every plant in your garden may save you money"—M. KENNY, *Westbye, Cambridge*.

buzzards and kestrels, are annually destroyed, all for the sake of the alien pheasant. If a pair of stoats or weasels would only make their home in my garden, I do not think I should be troubled much more with either the meadow mouse or the long-tailed field mouse, though the latter is nothing like such a pest here as the former.—I. BIGG-WITHER, *Birdwood, Wells, Somerset*.

—As you gave a little prominence to my experience with *Antirrhinums* (issue October 30, page 527) which I brought before the scientific committee of the Royal Horticultural Society, permit me to amplify the notice which appeared. The spikes of Yellow King (Barr) are very tall, 3 feet or more. It is the best deep yellow tall *Antirrhinum* on the market, and my firm has grown it specially for seed for the last two years. Our experience has been the same in 1914 and 1915. Some animal—we do not know what, but it was suggested by several members of the scien-

A SEPTEMBER SCENE AT THE CAPE OF GOOD HOPE. DIMORPHOTHECA PLUVIALIS IN THE GRASS.

Antirrhinums Eaten by Animals.—I was interested to see the note about the short-tailed field mice eating *Antirrhinums*. I have been greatly troubled by these mice in my rockery for several years past. Here they not only attack the seeds of the *Antirrhinum*, but gnaw through the stalk of the plant an inch or so above the ground level. Last autumn I planted out a few dozen in different parts of the rockery, and with one exception all were eaten down by these mice during the winter. This autumn I find they have commenced eating through the stems of *Ceratostigma plumbaginoides*. I have caught in this rockery alone twenty-three meadow mice (*Microtus agrestis*) since the beginning of the year. These mice seem to be much on the increase, for which our gamekeepers are chiefly responsible; and personally I think it is a great pity that so many of our mouse-eating birds, such as owls,

tific committee that it must be the field mouse—gnaws the stem through at distances varying from 3 inches to 12 inches above the ground, and after the stems tumble down flat the half-ripened pods of seed are eaten. Very clever, but quite annoying. The Yellow King variety is the only one that has been attacked, although between twenty and thirty sorts are grown.—W. CUTHBERTSON (of Dobbie and Co.).

FORTHCOMING EVENTS.

November 19.—Scottish Horticultural Association's Chrysanthemum Exhibition, Waverley Market, Edinburgh (two days).

December 8.—Perpetual-Flowering Carnation Society's Show, 12 noon to 5 p.m., Royal Horticultural Society's Hall, Vincent Square, Westminster.

THE NANKEEN LILY.

By SIR HERBERT MAXWELL, BART.

THIS beautiful plant has been endowed by various authorities with three different scientific titles, namely, *Lilium excelsum*, *L. isabellinum* and *L. testaceum*, meaning, respectively, the tall, the isabelline and the brick-coloured Lily. Now, whereas it is tall, and its flowers are of the soft tint known in French as "isabelle," and are in no sense brick-coloured,

The bulbs should be planted early, not later than the middle of September. They should be set just below the surface, in a sheltered position moderately exposed to the sun, and with a liberal admixture of lime in a soil composed of loam and leaf-mould. The result in the first year will probably be indifferent, perhaps disappointing. Careful watch should be kept for that fell fungus *Botrytis*, which is the chief enemy of this Lily, as it is of its reputed parents. If it makes its appearance, the foliage should be well and frequently sprayed, for it is worth much pains to get this Lily established in health. Once that is achieved, only the lapse of years is wanted to

C. iridiflorus in scientific language; for it is not found in Asia Minor as its correct, because earliest, specific name of *byzantinus* should imply, but grows in Hungary, and the later and therefore discarded specific *iridiflorus* is so singularly apt. If only it were better known in our gardens, we might call it in familiar English the Iris Crocus. It is because it is so seldom grown, and yet is so well deserving of a place in every rock garden, that I pen this note.

The foot of a slope facing north or north-west, on which *Ramondias*, *Primulas*, *Saxifrages* and such-like treasures create colour and interest in the spring and summer, is often bare and dull

in October, and hard to furnish with any late-flowering plant, that is not addicted to unmannerly habits of "scrouging" and smothering its neighbours. This precious Crocus is exactly fitted for such a position, as it loves a cooler and more shaded home than all others save *C. Scharo-janii*, the orange wonder of early August, and although its leaves in their spring heyday are rather wide, they are not numerous, nor does this species form closely crowded colonies.

It seems to me that it increases more by adventitious buds formed on the edge of the corms than in the orthodox Crocus habit of producing twins or triplets on the apex, so that by planting a dozen corms here and there in the open spaces between choice plants it is not likely the long grassy leaves will ever prove a nuisance. And the flowers in October! How can I sufficiently praise them. I have been admiring several small colonies of them to-day (October 27) and cannot say which I prefer—some extra large forms raised by the late Mr. Allen, famous for being the raiser of so many good *Snowdrops* and *Chionoscillas*; or the wild collected forms, not so large, but equally lovely in colour; or the

pure white one sent me some years back by Mr. Van Tubergen of Haarlem.

In sunlight the three large outer segments open out till they stand out nearly horizontally, showing the inner segments, which are less than a quarter as large, and often of a much paler shade. These inner segments stand up stiffly, and are so narrow and pointed that they are no bad imitation of the standards of some Iris.

THE CENTURY PLANT.

(*AGAVE AMERICANA*.)

The flowering of the Century Plant is always a matter of great interest, and we are much indebted to Sir Thomas S. Bazley, Kilmorie, Torquay, for so kindly sending the following note, together with a photograph, from which our illustration on page 555 has been prepared.

"The stem of the *Agave* (*A. americana*) now in flower here became evident last April, and soon looked like a gigantic *Asparagus* head. The growth was rapid to begin with (in one week it was 12 inches); it is now 26 feet high, both by measurement and calculation.

THE NANKEEN LILY (*LILIUM TESTACEUM*) IN THE CAMBRIDGE BOTANIC GARDEN.

it is to be regretted that in the "Kew Hand List" it is registered under the least appropriate of these names—*Lilium testaceum*. The popular English name for it, the Nankeen Lily, is happier, for nankeen is a dye approaching pretty closely to the delicate pale apricot, with just a hint of flesh colour, that distinguishes this Lily from all others.

Nobody knows its origin, for it has not been found in a wild state. It is said that it first appeared among a consignment of Asiatic bulbs more than sixty years ago, and it is supposed to be a natural hybrid between the Madonna Lily (*L. candidum*) and the scarlet *L. chalcedonicum*. If that be so, the alliance must be accounted among the most felicitous, for the offspring is one of the loveliest of the genus, of robust constitution, simple in its cultural requirements and, once established, sure to increase.

The usual stature of this Lily is from 4 feet to 5 feet; the stem is stiff enough to do without staking (no small merit), and is densely clothed throughout its length with linear leaves spirally set. The flowers are borne at the top of the stem in trusses of six to twelve blooms. The scarlet anthers form a charming contrast with the buff-coloured petals, which are gracefully reflexed.

produce a group like that in the Cambridge Botanic Garden, shown in the illustration herewith.

CROCUS BYZANTINUS.

By E. A. BOWLES, M.A., F.L.S.

THERE is always a great charm added to any flower's good points when one of them consists of a resemblance to some totally distinct plant. An Anemone-flowered Chrysanthemum, a Cactus Dahlia or an Orchid-flowered Canna appeals to our love of contrast and the unfamiliar at the first sight, and even when the race is well known to us we still enjoy any increase in their mimicry of forms not naturally their own. Those I have instanced are all florists' flowers of garden origin, but there is a species of Crocus that has such a likeness to a bloom of *Iris unguicularis* that it attracts all who see it, not only by its strange aspect as a Crocus, but also because it possesses so much of the beauty of the Iris. It is a great pity it cannot be called

"A popular delusion is that this species flowers once in a hundred years, but it only flowers once (in this instance from thirty to fifty years after planting), and then dies, unfortunately. The thick, succulent leaves of the plant here soon showed signs of the demand upon them for sap by the immense inflorescence; they are now flabby and emaciated, and will no doubt perish by the end of this year. The stem appears to remain, like a spar, for there is an old one here, woody but very light, said to have been produced in these gardens fifteen years ago.

"The flowers are peculiar, having anthers and stamens, but no distinguishable petals, giving a tasselled appearance. There are two similar plants, likewise flowering, about a mile distant."

LATE - FLOWERING TULIPS.

BY THE REV. JOSEPH JACOB.

THE Tulip is a flower well known, especially the more common kinds thereof, but there are many noble varieties, whose faces, as few are acquainted with, as with their excellent qualities." These are the opening words in the chapter dealing with Tulips in John Rea's "Flora" of 1665. I have chosen them for my text, for they are equally true in 1915. Two phrases particularly claim our attention—"noble varieties" and "excellent qualities." We will deal with them in the above order.

"Noble varieties."—Noble; Rea would have been hard put to it to find a more appropriate epithet wherewith to describe either a bed or a clump when these flowers are in full bloom. There is something in their bearing that we habitually associate with this word, whether we are looking at the sombre sumptuousness of a Louis XIV. or the bright brilliance of a Petrus Hondius. There is a majesty in the great tall flowers which few others have quite in the same way. Even in those whose stature is low, even in a flaming Golden Crown or in a glowing Glare of the Garden, or in soldier's red Marksman the same look is apparent.

Few are the varieties in which it is not found. Even then the pale retroflexa or the blushing Picotee have a Benjamin's portion of grace, and graceful carriage is next to noble bearing.

Varieties Whose Faces Few are Acquainted With.—Here follows a list of some of those of which the above heading is approximately true—garden Solomons, of course, excluded.

Dasystemon.—A dwarf, branched, low-growing plant of from 4 inches to 6 inches in height, with pure white flowers with large yellow centres and pointed petals, several of which are produced on each stem. No rockwork should be without a few, any more than it should be without a Saxifrage. It is a good doer and seeds freely. It

must be looked for in catalogues under the head of "species."

Louis XIV.—This to me is one of the Tulips of Tulips. I can imagine myself saving and scraping in order to possess a few bulbs as Mary Jones did for her Bible. Its rich plum purple and brown bronze is the high water of refined and rich colouring. Its large size is emblematic of contentment and good humour, for it can take things as they come and be happy anywhere. Why,

anything "from £500 to £1,000." *Tempora mutantur.*

Prince Hendrik.—I do not wish to frighten anyone, but this is a much more expensive variety than the last, or, to be accurate, one should have said *will be*, because as far as I know it is not to be found in any British list. When it is, all who appreciate refinement should buy a few bulbs, if the contents of their purses allow it. It is an exceedingly attractive rectified byblømen—a pure white of fine form and large size, with its pretty purple colouring entirely confined to a narrow beam running up the centre of each petal. When it flowers next spring I will have wintered and summered it, and I will then be able to say if what is stated about its behaviour is correct, viz., that its markings are constant. Holmes' King, which is figured on page 161 of Sweet's "Florist's Guide," Vol. II. (1829-1832), is its counterpart. It is the only one of the type pictured in that work, which probably means that then as now it was very uncommon.

Mrs. Kerrell.—A Cottage variety of medium height with somewhat long pointed flowers of a delightful warm pink, which has more than a suspicion of silvery amber in its composition. This, as Tulips go, is still expensive, but as it is a good increaser, the time will soon come when the price will be lower.

Marksman.—A bright scarlet Cottage Tulip which in its own shade of colour stands out alone. As the correspondence about colour charts (THE GARDEN, October 9, page 501) shows, we need more exactness in their definition. In the scarlet of Marksman there is a considerable amount of orange, which seemed to be more noticeable last spring than usual. The plant is of medium height, and the self-coloured flowers are of a nice size and not given to "breaking." I look upon this as one of our best Tulips.

Cassandra is another variety of medium height (that is, from 16 inches to 20 inches) of a most distinct tone of bright rose or possibly carmine rose. The flowers are self coloured and are remarkably lasting. This variety does not seem to be anything like so well known as its merits warrant. It is not expensive, being somewhere about 3s. or 3s. 6d. a dozen.

Valentin is quite one of the best of the Darwin class. It is a tall grower and has large, round flowers of a soft grey toned purple, which becomes considerably lighter with age. It is one of the first to bloom, following close upon the heels of what might so aptly be termed,

to use an old designation, the "medios" like Le Rêve and Couleur Cardinal. I have an idea that if anyone is looking out for a novel and pleasing combination, a bed of Valentin, bordered with the dark glossy Fra Angelico, would be effective; but as one learnt from the great Tulip exhibition at Vincent Square, one has to be most careful in fixing up matches and contrasts in colour schemes.

Eliphant, called also **Oliphant** (so I believe, at least, from the descriptions which seem to tally

A CENTURY PLANT, AGAVE AMERICANA, FLOWERING IN SIR THOMAS BAZLEY'S GARDEN AT TORQUAY.

then, is it, being as it is an old variety, so high priced? It is as if it were hand made—a thing impossible to produce by any process of machinery. It was rather a shock to see it listed in one catalogue at the low (for it) price of half a guinea a dozen. In the majority it figures at a guinea or more. But let me say that there are very few varieties indeed that mean a pound or more when a dozen are bought. A small book of the year 1840, called "The Gardener's Manual," airily states that "a prime bed of Tulips" costs

with one another in the Dutch lists, aided also by a small modicum of common sense), is a plant with a great future, judging by appearances. I saw it at the Wisley trials for the first time this year. It is very tall and large, and on this account, and also because of its very suggestive colouring, I think the name should undoubtedly be Eliphant—no other could be more appropriate; but when doctors differ, what is a simple layman to say? Perhaps, should these lines meet the eye of Mr. Jan Roes, the Tulip walking dictionary of Holland, he would kindly favour *THE GARDEN* with a note about it.

Tara (very likely synonymous with William Goldring) is a fine representative of the deep shaded rich ruby reds. Sturdy in appearance and fairly tall in growth, it is a striking object in a bed in a mixed herbaceous border, or in a mass by itself in an isolated position. I fancy Tara is a name given to it in Ireland, but if it is, the choice is most significant, as few other places mean so much to the natives of our Sister Isle. It recalls "the pride of former days" as few others do, and Tara's halls and Tara's walls live and live again in the contemplation of this Tulip gem. It has a serious rival in

The International, and if fuller knowledge and more intimate familiarity compel us to award the palm of contest to the newer comer, I could wish, were it permissible, that its name should be changed from the unmeaning mouthful by which it is at present known to Tara's modern successor, "Dublin"—dear dirty Dublin.

Millet is a Darwin variety which for some unaccountable reason has never been "cracked up," as the colloquial phrase goes, as it should have been. It has a large, deep crimson flower, very shapely and with good lasting properties. It is late in blooming and would make a grand contrast with the Cottage, Leghorn Bonnet. As long since as 1906 it received an award of merit from the Royal Horticultural Society. From its present obscurity it might be thought that this is one of those marks of honour about which the least said the better. But it is not so. The boot is on the other leg. It is the public, and to some extent the writers in the horticultural Press, who have never appreciated this variety as they should have done. It is a low-priced variety, and if those who are on the look-out for something cheap and good will buy a few this year "just to try," I predict the majority will give a larger order in 1916, should the war have left us any pennies in our purses. The foregoing list includes Cottage Tulips, Darwin Tulips and a Tulip species, all of them extremely beautiful in their way, although none of them is known to anything like the extent their merits warrant. However, most, if not all, of them are appreciated by the *real* Tulip enthusiast.

SCABIOSA CAUCASICA:

THE CAUCASIAN PINCUSHION FLOWER.

SCABIOSA CAUCASICA.

THIS is one of the finest perennials; it comes into bloom at a time when its flowers are welcome. In point of beauty and utility, as much from the distinct form of the flower as for its refined and exceptional colour, this handsome plant occupies a unique position. Fortunately, too, for those who appreciate good gardening and good flowers, there are not many obstacles in the path for those who would do justice to this plant, and there is, therefore, no reason why it may not be grown with a full measure of success by all who so desire. Perhaps the chief item—looking at the matter merely from the cultural standpoint—is that of keeping an eye upon the stock, as in some soils more than others the plant begins to yield smaller flowers after the second year. This is not the case in all soils; indeed, it is not so in the exceptionally light and well-drained soils of Hampton

and district. Yet in others I know there is a decided tendency in the direction I have stated. By far the best results are obtained, where it is possible to do so, by raising seedlings for one's self, and putting the small plants out in rich or good land at quite an early date—that is to say, sow a sprinkling of seed in early autumn as soon as fully ripe, and grow the seedling plants quickly as well as liberally from the start. Such seedlings will be best grown in a cold, freely ventilated frame for the winter that follows, and if any are large enough they may be potted singly. Then by the end of February the largest should be in the open ground, for it is one of the mistakes of this class of culture to keep small seedling plants long confined in small pots and a much smaller portion of a almost always too dry soil.

Such conditions—and they more frequently exist than many surmise, to the detriment of future progress—should be minimised as much as possible as among the intolerable evils to successful plant culture, and equally annoying and

disheartening to the amateur who longs to do his best, and yet is struggling hard against some unseen foe. Often the seedling that is starved and becomes hide-bound in infancy is not a success, and the grower of it wonders why, seeing he has faithfully followed the instructions laid down for its general cultivation. In justice to many hardy plant specialists it must be stated these are doing their best to help by adopting this very simple routine in growing many plants for sale; but then, the nurseryman has to cater for a variety of customers, and those who come late, often very late, do not obtain the fine plants from the ground, but a much smaller one in a pot. That plant may have been in that pot for one month or a dozen, which makes all the difference when it is eventually planted out. It is those and only those who take care, whether it be seedling or rooted cutting, to plant always in the youthful days that know and appreciate the value of such timely work. I make a point of impressing its necessity here because this Scabiosa is one of those things most decidedly benefited by such timely assistance. At the same time, quite good-sized plants of this may be transplanted if need be. Quite naturally, the plant is better without the shift, though if it be done quite early in the spring, the loss will be small; and what is true

of the beautiful mauve or lavender shaded kind is equally true of the white kind, which for all purposes is a most valuable plant. Some have complained that the white is not pure, which is certainly true.

Those who have been unsuccessful in raising seedlings of either white or blue kinds should remember that great value attaches to quite ripe and fresh seeds, the latter, when allowed to remain on the plant to the "shedding" stage, being generally most reliable in growth. The plant, too, is much assisted by slight warmth when raising the seedlings. Seed of this may soon lose some of its power if kept in a very dry and much heated room. The blue Scabiosa, when well grown, will attain nearly 3 feet in height, the heads of bloom appearing on long footstalks from amid handsome, well-marked leafage, the white variety being a counterpart save in the matter of colour. The former came into cultivation over a century ago, viz., 1803, and, besides its white form, there have been described one or two varieties which for all practical purposes may frequently be taken from any large bed of seedling plants. The variety *magnifica*, however, is of outstanding merit. The flowers are deep lavender blue and delightfully frilled at the margin. This variety received an Award of Merit from the Royal Horticultural Society when first shown by Messrs. Cocker of Aberdeen about two years ago.

PLANTING HARDY RHODODENDRONS.

FEW trees and shrubs, if any, are more exacting in their requirements than Rhododendrons. There are certain conditions of the soil of which they are most impatient. For instance, they will not tolerate a sour soil or one containing an excess of lime, neither will they succeed in a soil that is liable to become too dry on the surface. As we are now on the threshold of the planting season, it is well that we should give due consideration to the likes and dislikes of these, the most beautiful of all hardy evergreen shrubs. Rhododendrons love moisture and shade. They like moisture overhead as well as at the roots. They are shallow rooting, and if the surface of the soil becomes parched it may be fatal to them, while the spade and hoe should not be used near to their roots.

In places where Birch trees, Pines and Heather abound, Rhododendrons are almost sure to thrive. At Bignor Park they grow and flower beautifully under the partial shade of Cedars and backed with Evergreen Oaks. *Rhododendron ponticum* is often grown as a covert shrub. It makes a splendid

RHODODENDRONS UNDER THE PARTIAL SHADE OF EVERGREEN OAKS AND CEDARS AT BIGNOR PARK.

undergrowth to Birch, Spanish Chestnut and conifers, and is one of the few shrubs not attacked by hares. In dense shade, however, the Rhododendron does not flower at all freely.

No one has yet been able to explain why Rhododendrons show a marked dislike to the presence of lime, although the subject has been widely discussed. The writer is acquainted with a garden on the slopes of the chalk downs of Berkshire, where repeated attempts have been made to grow Rhododendrons. Before planting, large beds were excavated and filled with peat and Bagshot loam. For the first two years the Rhododendrons grew satisfactorily, but later, when the beds were doubtless permeated by the surrounding chalk, the plants eked out a meagre existence and were afterwards grubbed up and burnt. Not profiting by experience, the experiment was renewed a few years later, with the same disastrous results. Now, to excavate beds in unsuitable soil is an altogether wrong procedure, for sooner or later the injurious element is certain to reach the roots of the plants. A far better plan, if Rhododendrons are to be grown on unsuitable soils, is to raise the beds to form a bank, making the outside secure by forming walls of turves.

Rhododendrons grow quite well in a fibrous loam, even without an addition of peat. Clayey soils are improved by the addition of peat and leaf-soil. It is a mistake to make up a soil with too much light material, such as sand and leaf-mould, which would soon become dust dry in a spell of hot weather. Leaves form a natural surface mulch and should always be present, while the addition of cow-manure is beneficial to established plants.

October and November are two good months for planting Rhododendrons, but they may be planted any time up to the end of April, providing the weather is open, for they must not be lifted on the approach of frost. The following varieties are quite hardy; they should be planted about 6 feet apart, to save replanting a year or two later on:

Pink.—Pink Pearl, Kate Waterer, Alice, Mrs. E. C. Stirling, Gomer Waterer and Fair Rosamund.

Red.—Doncaster, Charles Bagley, John Waterer and James Marshall Brooks.

White.—Baroness H. Schröder and Mrs. J. Waterer.

Purple.—Everestianum, Othello, and fastuosum (of which there is a double form, flore plenum).

Bicolour.—Sappho, Helen Waterer and Marchioness of Lansdowne.

Rhododendrons should be planted to form bold, natural groups on banks, in glens, or on the outskirts of the woodland. To place them in small formal beds is to lose half the charm of these noble shrubs.

C. Q.

THE ITALIAN STARWORTS.

The flowers of the Italian Starworts are larger than most Michaelmas Daisies and stand out very conspicuous particularly when associated with Japanese Anemones or similar subjects, either when growing or as cut flowers. Being only about 2 feet high they are very suitable for small gardens where space will not allow the taller Michaelmas Daisies to be grown, while bold masses in larger gardens are very effective. Bessarabicus, King George, latifolius Riverslea, Perle-Rose, Perry's Favourite and Stella, are a few of the best varieties.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Peaches and Nectarines.—If a suitable house is available for growing pot trees, this method should be adopted for producing the earliest crops. If the wood is perfectly matured, the trees may be pruned, cleaned, and placed in the house at once. If the young growth was regulated and stopped in the growing season, little pruning will be required now beyond thinning out the weak wood and shortening that which is extra strong. For the first two or three weeks fire-heat must not be used, but every advantage must be taken of the little sun-heat which is obtainable during the winter months. Lightly spray the trees with rain-water on fine days, and sprinkle the floors and paths as often as necessary. Water the roots with extreme care till growth is active; but when water is necessary, give sufficient to thoroughly soak the soil.

Late and Midseason Trees.—The work of pruning, cleaning and training Peach trees under glass should, if possible, be completed before the turn of the year. Any trees which have produced unsatisfactory crops should be examined at the roots and any defects made good. In pruning old trees, first examine the old branches and cut out any which are becoming bare of fruiting wood. Before training the trees, thoroughly wash the house with strong soapy water; then treat the trees in the same manner, being careful not to damage the buds. When the trees have been trained, remove 2 inches or 3 inches of the surface soil from the borders and replace it with a mixture of loam, wood-ashes and crushed bones. See that the trees do not suffer for want of moisture at the roots, especially where the latter are confined to inside borders. In order to give the trees a thorough rest, the ventilators should be thrown open as much as possible.

Plants Under Glass.

Luculia gratissima.—This beautiful greenhouse shrub should be grown in every garden where a suitable house is available. A cool greenhouse is the most suitable structure in which to grow it, and if a restricted border can be provided to accommodate its roots, so much the better. After flowering, which is usually by the end of the present month, the old wood must be cut hard back. The plants should then be induced to rest by keeping the roots on the dry side and the house as cool as possible.

Early Flowering Bulbs.—Roman Hyacinths and the early white Narcissus promise to flower unusually early this season. They must be kept in cold frames unless they are required to flower before Christmas. Bulbs which have been taken from the ash-bed must be protected from rats and mice. These pests are very destructive if allowed to go unchecked.

The Flower Garden.

Perpetual-Flowering Carnations.—These Carnations are fast becoming popular for bedding. Plants which were rooted for this purpose a few weeks ago must be kept near the glass, so that they may be as sturdy as possible. No effort must be made to force growth till the turn of the year. When the pots are full of roots, shift them into 5-inch pots.

Perennial Asters.—The mixed border would be dull indeed during late autumn without the Michaelmas Daisy, and there are so many beautiful varieties now that the old forms are fast dying out. To obtain the full beauty of these plants they should be dug up and replanted every season, selecting only the most promising pieces for re-setting. Apart from including them in the mixed border, there are many other places where they may be planted with equally good effect.

Marguerite Mrs. F. Sander.—This has proved most useful in the flower garden. There is no white flowering subject that I know to equal it for its long season of flowering, and it seems to thrive in all kinds of weather. It is easily propagated from cuttings, which may be inserted at any time when available. To obtain suitable growths for cuttings, a few old plants should be potted up and partially cut back. Place them in

a warm, moist house, where they will quickly make healthy growth.

The Hardy Fruit Garden.

Gooseberries.—The cuttings which were struck last year may now be placed in their permanent quarters. The ground should be well prepared by trenching and manuring. Should the soil be poor, a quantity of chopped loam should be placed round each plant. The pruning of Gooseberries may be done now; in fact, the pruning of all kinds of fruit trees should be forwarded as much as possible. Old Gooseberry bushes must be well thinned out; and where there is a young shoot to replace an old branch, this should be left, for it is on the young growths that the finest fruits are obtained. The system of growing Gooseberries on a wire trellis is excellent, as the very best dessert fruits are obtained from this method. The trees must, of course, be trained as cordons. If necessary, cuttings may be inserted now for propagating young trees.

The Kitchen Garden.

Spinach.—The strongest leaves must be kept picked off the plants to encourage fresh growth. Keep the plants free from decaying leaves and weeds, and to further encourage healthy growth, hoe between the rows when the ground is in a suitable condition.

Jerusalem Artichokes.—Cut down the stems of these plants and burn them. Dig up a portion of the crop for present use and store in sand in a cool shed.

Peas.—If Peas are required at the earliest possible date, a batch may be grown in pots or boxes. The seed may be sown towards the end of this month in 8-inch or 10-inch pots. A compost of loam, leaf-soil and manure from an old spent Mushroom-bed will be suitable. The seedlings must be well thinned out when through the soil, and be grown as sturdily as possible.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Asparagus.—As soon as the foliage is ripe, the growths must be cut over, afterwards clearing the weeds from the beds. The small pathways between the beds should be hoed and all rubbish raked off. This will leave the whole tidy, as it should be for the winter season.

Cabbage.—Seize any favourable opportunity, when the condition of the ground will allow, to hoe over the spring Cabbage plot. At the same time make secure any of the larger plants which may have become loosened by the wind.

Seakale.—If this has been subjected to a severe frost, there will not be the same difficulty in forcing it; but when the weather has been mild, progress will be very slow. It is therefore better to wait until there has been frost. The Mushroom-house is the most convenient place to grow it, but anywhere in the dark where there are heat and moisture it will succeed.

Parsley.—The older leaves should still be freely removed for use when required, to allow the young leaves to develop. Where plants are lifted into frames for the winter supply, sufficient space should be left between the plants to prevent damping of the foliage, which is likely to happen when there is overcrowding.

The Hardy Fruit Garden.

Root-Pruning.—When circumstances allow, this operation should be done at this season. Many unfruitful trees can be brought into a bearing condition by a timely pruning of the roots. There is no hard and fast rule of the extent to be pruned, as the size and condition of each tree may require different treatment. In many cases it may be offending taproots which require removal. The improvement in fruiting will generally be noticeable in the second season following. When exposing the roots for this treatment, the opportunity should be taken to add new soil; this should consist of good loam and lime rubble.

Fruit Under Glass.

Pot Vines.—For supplying very early fruit in May, it is essential to have stout as well as thoroughly ripened canes. A mild bottom-heat is necessary; this can be obtained either with a gentle hot-bed made up of leaves mixed with stable litter, or by hot-water pipes arranged under the bed or stage where they are to be grown. Black Hamburg is the most reliable kind, and it also matures before any of the other better-class varieties. After the Vines have been got into position the forcing must commence gradually, a temperature of 50° being sufficient at night; it can be advanced to 55° and 60° in the daytime. In bright weather the Vines may be syringed two or three times a day, but less frequently in cold, dull weather.

The Flower Garden.

Hollyhocks.—In wet and cold districts these plants are very liable to be lost during a spell of

forward plants should be pinched out. Where the stock of any particular variety is limited, this can be used as cuttings, as they root readily even at this season.

Bulbs.—Any planting of bulbs which has been unavoidably delayed should be completed as quickly as possible before the bulbs lose any more of their vitality.

Plants Under Glass.

Arums.—Since the early batch of plants is now in flower, some encouragement should be given to the succeeding growths to produce large spathes. This is only brought about by good treatment. Liquid manure and fertilisers should be used in alternate applications of water, as the plants are gross feeders. Green fly is frequently troublesome, even in the depth of winter, and, if not got rid of in time, many flowers will be spoilt. A fumigation should be given without delay whenever any trace of this pest has been discovered.

on the foliage. Some growths may require tying, but pruning, where necessary, is best left alone until the flowering season is over.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

THE SUNK GARDEN AT REGAL LODGE, KENTFORD.

ON this page we illustrate the beautiful sunk garden as seen from the loggia in Lady de Bathe's garden at Regal Lodge, Kentford. It has been designed in perfect taste, and laid out with consummate skill. It is, in fact, an artist's corner,

LADY DE BATHE'S SUNK GARDEN AT REGAL LODGE, KENTFORD.

severe frost. Either leaves or straw can be used to protect them, but they should not entirely cover the plants, merely surrounding the base of the stems, which should now be shortened if this has not already been done.

Rock Garden.—Many subjects in this quarter will require some sort of protection from frost. The most convenient to use are ashes for the small subjects, as these not only protect from frost, but act as a preventive against raids by slugs.

Bedding Plants which are wintering in frames should be carefully attended to daily as regards ventilation and, when necessary, water. This in most cases will be seldom required, there being so little evaporation at this time of the year. No risks should be run by neglecting to cover up the plants when frost is possible.

Pentstemons.—Cuttings which were inserted in September have now grown 3 inches or 4 inches in height. In order to get more bushy plants for setting out in spring, the points of all the most

Resting Plants.—Such tuberous-rooted plants as Begonias, Caladiums, Achimenes and Gloxinias having now died down, the pots can be laid on their sides under a greenhouse stage where the temperature is not likely to drop much below 50°.

Solanum Capsicastrum.—As the berries commence to colour, the plants should be kept in a slightly warmer atmosphere than that in which they have been previously growing. Being very subject to attacks from insect pests, these plants should be fumigated fairly frequently.

Bouvardias.—These plants may now be kept in a slightly higher temperature if they are required to flower early. The atmosphere should not be allowed to get too dry, or red spider will become troublesome, Bouvardias being very subject to its attack.

Camellias.—Until the flowers commence opening, the syringe should be used freely to help to keep down the various forms of filth which accumulate

perfect in point of colour and grouping, blending unconsciously into the outer garden without undue formality or any leaning towards overcrowding. In the centre is a Lily pool, where Nymphæas thrive and the stippled stems of Scirpus lacustris zebrina are reflected in the placid water with charming effect. It is a paved garden, and little tufts of Sea Pinks, Saxifrages, Thyme and Wall Campanula grow between the large paving-stones. Beds of Roses and Lilies edged with that lovely mauve Viola Maggie Mott lend pleasing colour to this enchanted garden. Large earthenware vases filled with double white Marguerites occupy a prominent position, while in the background are standard Heliotropes, large Orange trees in tubs, and pillars draped with Roses.

THE FOUR BEST DESSERT APPLES.

MANY of the failures and disappointments among amateur fruit-growers can be traced to a poor selection of varieties in the first place. Too much importance cannot be attached to a careful and judicious selection of the fruits for a small garden, or much subsequent care and labour will simply cause disappointment. There can be nothing more annoying to the owner of a small garden than the discovery that the Apple or Pear or Plum trees upon which he has lavished so much attention and spent a certain amount of money are of inferior or unsuitable varieties. It is always rather an unsatisfactory matter to recommend a few varieties, say, of Apples, and to say that they are the best, for some varieties succeed far better in certain localities than in others, owing to some conditions of soil or climate, or both, that happen to suit

6 inches deep and have a diameter of at least 4 feet. A hole of this size allows of the roots being spread out properly, and still gives some broken ground, into which they root more easily than in the hard, undisturbed soil. Although the hole is made 2½ feet deep, it does not follow that the tree must be put in at that depth. An excellent guide as to the depth to plant is given by the soil mark on the stem; this shows clearly how deep the tree has been previously, and it should be planted at about the same depth or a little higher so as to allow for the settling of the tree. To ensure this being done, sufficient fresh turfy soil must be placed in the bottom of the hole to bring the tree to its proper level. It is important that the soil be trodden firm, although it must not be made hard. Then, having the roots carefully spread out (preferably in two separate layers if they are numerous, rather than putting all on the same level), they are covered with fresh turfy soil, which is made firm as the work of filling in proceeds. It is best to place fresh soil immediately about the roots; then the remaining space can be filled in with the soil taken out.

St. Edmund's Pippin is an Apple that is not so well known as the others named, yet it has many good points. In the first place, it is an early Apple, for it is ripe in October, and it is of far better flavour than many early Apples. Russet Apples are great favourites with many, their rich Russet flavour being both distinct and agreeable. St. Edmund's Pippin must be classed as one of the best Russets. It is not such an attractive Apple as some, being of medium size and of dull yellow russet colouring. St. Edmund's Pippin fruits freely as a bush tree on the dwarfing stock, and may be confidently recommended for dessert during October.

Cox's Orange Pippin.—There is no Apple in cultivation that is so richly flavoured as this, and it is without exception a general favourite. It thrives well as a bush tree on the Paradise stock, and succeeds in all except cold soils. Cox's Orange Pippin is generally at its best towards the end of November and until Christmas. It may be kept for some time after Christmas in a well-constructed fruit-room, but as a rule the flavour deteriorates in the new year. It is essentially an

Apple to eat before or about Christmas-time. In the extreme North of England and in Scotland this delicious Apple needs the shelter of a wall to be had at its best, but it is well worth any special attention it may have in this way.

Allington Pippin.—This is an Apple that has become extremely popular in

APPLE KING OF THE PIPPINS.

APPLE ALLINGTON PIPPIN.

certain sorts. It is, then, in no dogmatic spirit that the four varieties of dessert Apples shown in the accompanying illustrations are recommended as the best. Probably for the majority of amateur gardeners it would be difficult to find four that would prove more satisfactory, but, before planting, everyone should take the precaution to find out from some neighbouring garden whether or not any of the Apples mentioned here are known to be unsuitable to the district. If all are found to be suitable, then I venture to give these four as the best. However, I would like to say that if any other good variety does especially well in the neighbourhood—and this is sometimes the case—then I would suggest that it be added to the collection. After a careful selection of varieties, too much importance can hardly be placed on the

Ground Preparation and Planting. Fruit trees are planted not for a year or two, but perhaps for generations, and it is evident that time spent in giving them a good start is time spent unusually well. A large hole should be dug out for each tree; it should be made not less than 2 feet

Unless the planting is firmly done, the trees will never be seen at their best.

Time to Plant.—A good general guide to the time of planting fruit trees is to be found in the fall of the leaf. The best time is generally admitted to be when most of the leaves have fallen, but while a few still remain on the tree. The trees are in this condition, as a rule, in November, and this is the month for fruit tree planting. It is by far the best plan to dig the hole a few weeks before and fill it up again. The soil will have settled by planting-time, and, so long as it has been dug previously, the actual hole to receive the tree need be no larger than necessary. There must still be room for the roots to be spread out horizontally. All the varieties of Apple now mentioned are to be grown as bush trees on the broad-leaved Paradise or dwarfing stock. It is known as the dwarfing stock because its characteristic is to make a mass of fibrous roots not far from the surface, and thus bring the trees into good and regular bearing within a very few years. All nurserymen grow bush Apple trees on this stock very largely, and there is no difficulty whatever in obtaining them.

a comparatively short space of time so far as the age of Apples is concerned, for it has only been on the market since 1896, whereas Apple Cox's Orange Pippin was introduced forty-two years earlier. It may be said to rank next to Apple Cox's Orange Pippin in sweetness and richness of flavour. It is a larger fruit than the latter and more beautiful to look upon. It is one of the very best Apples for a small garden, because not only is it a first-rate sort so far as dessert qualities are concerned, but it begins to bear heavy crops of fruit when the trees are quite small; in fact, I know of no Apple that will give such a good crop of fruit from young trees as Allington Pippin does. On looking through a large collection of fruit trees about three years old some weeks ago, this characteristic of Allington Pippin was most marked. This is really an excellent amateur's fruit on the Paradise stock. It is in season longer than Cox's Orange Pippin, for while, as I have said, the latter is at its best not later than Christmas, Allington Pippin is quite good from November to February.

APPLE ST. EDMUND'S PIPPIN.

King of the Pippins is an Apple that can claim to be a most satisfactory one, since it rarely or never fails to give a good crop. The fruits are handsome, and command a good price in the market. The flesh of this variety is somewhat soft and the flavour mellow rather than sweet, and for these reasons the fruits offer a most agreeable change from sweeter Apples, while, of course, many actually prefer an Apple of this kind. It should be obtained as a bush on the Paradise stock, and then even on cold soil will bear regularly and well. The fruits are in season from October to Christmas, or even later. I have not thought it worth while to mention any very late Apples, for as a rule amateurs with small gardens have no convenience for storing them. Thus the four I have mentioned would give a supply of dessert fruits throughout October, November, December and January. I am sure that all four would be found to give full satisfaction. He would indeed be a man whose taste was difficult to please if such Apples as these, their season extending over four months, did not meet with his approval. W.

BLACK SPOT ON ROSES.

REFERRING to the recent correspondence on this subject, in my opinion this terrible disease is increasing rapidly among the Rose plantations in this country, owing to the fact that amateurs and Rose growers generally fail to see the necessity of taking measures to stamp out the disease on its first appearance. Mr. Mawley's method of removing and immediately burning each infected leaf on the first appearance is a good preventive if carried out thoroughly in every garden; but how few will take the trouble. It is, therefore, up to the enthusiast to take time by the forelock and prevent the appearance of this and other fungoids.

Nearly all fungoids have two stages, the active and the resting, and it is necessary to attack them at both periods. After much experimenting I have found that sulphate of iron is the most fatal chemical to use against the resting spores that remain on the branches and soil surface throughout the autumn and winter months. This should be applied in November and again in March in liquid form, dissolving 1lb. of the chemical

in 5 gallons of water free from lime. (If the water contains lime, 4 gallons will be sufficient.) The surface of the beds and the plants should first of all be cleared of mulchings, dead leaves, or anything else likely to harbour spores on the under surface, and therefore likely to escape contact with the iron solution. Watered through a fine-rosed can, 5 gallons, should roughly, cover 25 square yards. Against active spores I have found copper compounds only to be efficacious when applied monthly between March and October; but here the difficulty comes in of what copper compounds to use and how to cause the copper to adhere sufficiently long to penetrate into the

inner tissues of the foliage and stems without at the same time injuring or disfiguring them. I am both anxious and willing to send free samples and full directions to every interested grower of Roses who cares to write me fully on the subject.

Dunbryan, Formby, Lancs.

J. LYTLE.

WITH reference to the correspondence regarding black spot on Roses, I find that Grüss an Teplitz and La France '89 are chiefly attacked. I have not yet noticed it on Juliet or Soleil d'Or.

Forest Hill, S.E.

H. G. B.

WITH reference to your correspondence about black spot on Roses, perhaps my experience may be of interest. I never saw black spot until three or four years ago, and then it made its appearance on my Penzance Briars and quickly spread to my dwarf Roses until nearly all my Rose garden was leafless. I found sulphide of potassium, $\frac{1}{2}$ oz. to 2½ gallons of lukewarm water, a good spray to protect the second growth, but nothing has really helped my Roses so effectually as constant spraying with formaldehyde, one tablespoonful to a gallon of water. One year I was able to do this every week, and three times in winter I sprayed with a double strength solution (in the morning on a still, mild day), with very good results. I have never found anything to cure black spot, but constant spraying with formaldehyde and the burning, as much as possible, of all infected leaves will keep it in check.

The Penzance Briars are always very badly affected with me, and the Lyon Rose I simply cannot grow. I have tried over and over again and had magnificent blooms for a year or two, then black spot claims its victim and the plant dies.

MABEL A. GORDON DILL.

Lis-na-dill, Woodbury, Devon.

ANSWERS

TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWER.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

YEW HEDGE AND GALVANISED IRON (H. L. F.).—We have never tried the iron sheets with a view to restricting the rooting area, and have always found that a trench opened once in two years at 3 feet from the hedge to about 3 feet deep answered every purpose. We should not, however, hesitate to try it in circumstances where the trench was either impossible or inconvenient, and if you adopt it, we should advise 3 feet long sheets sunk in rather more than their full depth vertically at a few feet, though not less than 3 feet, from the hedge. If the latter is old and of considerable spread, it may be necessary to keep further away. The iron sheets are not likely to injure the hedge in any way. A good strong gauge of iron should be selected.

CHRYSANTHEMUM UNSATISFACTORY (Enquirer).—The leaves and stems of the variety Niveus which you have sent are not affected by rust, but by yellow thrips, which have eaten the stems and the under sides of the leaves very much. The pests suck the juices of the plant; then the skin dries and turns to a brown colour, forming a rough callus resembling the rust. Lay the plant on a mat and syringe it forcibly with a soapy solution, half an ounce of soft soap dissolved in a gallon of water.

ROSE GARDEN.

BLACK SPOT ON ROSES (Amateur).—We are very glad to hear that your Roses have been so successful. You are doing very wisely in collecting the fallen foliage and burning it, and it would be well to continue doing this and to remove and replace with fresh the top soil of your bed. The bushes should be sprayed in May next with Bordeaux mixture as a means of prevention, and again at the first onset of the trouble if it should reappear. If it occurs a little late in the season it does not weaken the bushes greatly; but when it occurs early and persists through the summer it has a very weakening effect.

MOVING ROSES AND HERBACEOUS PLANTS (F. Whiteway).—Unless your move next May is a local one, we should hardly advise your undertaking to move the plants at all, since a hundred Roses are so easily replaced that at the time of year named the plants would suffer considerably. If, however, you are bent on taking

APPLE COX'S ORANGE PIPPIN.

them with you, the safest plan for the Roses would be to presently lift them all and, having shortened the growth, heel them in again. Then quite late in April prune them hard back, and so prepare them for the move. The herbaceous plants could be moved by lifting now, detaching the most youthful and vigorous pieces from the outside of each clump, heeling them in the soil again, and cutting back in March. In this way you might save them. At the same time, you must be prepared for an all-round weakening effect and little, if any, flower next year. To lift, box and plunge the plants would not only entail considerable expense now, but would also mean additional expense in May, and, unless the collection was of considerable value, it would not be worth while.

FRUIT GARDEN.

PEAR KING EDWARD DECAYING BEFORE IT IS RIPE (R. R., *Godalming*).—The one sound fruit sent is ripe and excellent. The others are practically putrid pulp. The only likely cause which occurs to us of this untimely decay is that the fruit has been damaged by rough handling in gathering, or allowed to fall from the trees, and thus become bruised, and in consequence decomposition has set in. Pears cannot be handled too carefully. The slightest over-pressure of the fingers will cause decay to set in.

GRAPE MADRESFIELD COURT CRACKING (*Constant Reader*).—This is a failing to which this splendid Grape is subject, especially when the Vines are young, as in your case. Unlike Muscat Grapes generally, which luxuriate in a higher temperature than do other Grapes, Madresfield Court is an exception. This succeeds best under comparatively cool treatment, on similar lines to the Black Hamburgh. The cause of the cracking of the berry in the case of the Grape is now well known among gardeners, as also is the remedy to apply. It invariably takes place soon after the berries have stoned and the time for colouring approaches. The way to prevent it is to ventilate more freely, day and night, during this stage of the Vine's growth and, practically, until the colouring time is over. This will naturally cause the atmosphere to be cooler, and in consequence the swelling of the berries less rapid. Herein lies the secret of the cure. It is awkward for the Muscat of Alexandria when growing by the side of the Madresfield Court, and a compromise will have to be made by giving less air on the lights opposite the former, both top and bottom. A carpenter or handy-man can negotiate this for you.

MISCELLANEOUS.

LEATHER-JACKETS (*Brighton*).—The daddy-long-legs is always most abundant in places where water finds a difficulty in running away, and the drainage of such places is an aid to keeping the pest in check. Starlings, rooks and plover are also useful, for they eat numbers of grubs and flies. Manuring with sulphate of ammonia in spring, raking, so far as is possible, and then rolling with a heavy roller will do a good deal to check the pest; while in summer, when the flies are about, strewing crude naphthalene on the greens will probably act as a deterrent, driving the flies off and preventing them laying their eggs.

NAMES OF PLANTS.—*Enquirer*.—Bo'h the leaves of Ampelopsis might have been gathered from the same plant (A. Veit hii, syn. Vitis inconstans), as they vary a great deal. Information re Bottomley's Plant Food may be obtained from Professor Bottomley, University of London, King's College. It is now obtainable for garden use.

NAMES OF FRUIT.—*J. H.*—Lane's Prince Albert. —*Boris*.—1, Alfriston; 2, Yorkshire Beauty; 3, Cellini; 4, not recognised, poor specimen.—*Norah*.—1 and 2, New Hawthornden; 3, Blenheim Orange; 4, Stamford Pippin; 5, Washington; 6, Beurré Clairgeau.—*E. M. H.*—1, Reimette du Canada; 2, decayed; 3, King of the Pippins; 4, Court of Wick; 5, Beurré Dumont; 6, Hornmead Pearmain; 7, New Hawthornden; 8, Potts' Seedling; 9, Striped Beaufin; 10, Hall Door; 11, not included; 12, Warner's King.—*J. L. W.*—1, Lemon Pippin; 2, Duchess of Oldenburg; 3, King of the Pippins; 4, Lord Suffield; 5, Bismarck; 6, Ecklinville; 7, Hoary Mornin; 8, Hollandbury; 9, Striped Beaufin; 10, Princess.—*Mrs. Phillips*.—The Pear is deformed and out of character, but we believe it is Gilgil.—*H. H., Bristol*.—Pears: 1, decayed; 2, Beurré Diel; 3, Duchesse d'Angoulême; 4, Brown Beurré.

SOCIETIES.

AUCHENCAIRN HORTICULTURAL SOCIETY.

THE annual general meeting of this society was held in the Murray Hall, Auchencairn, N.B., a few days ago. The retiring president, the Rev. W. R. Henderson, presided over a good attendance of the members. The annual financial statement was submitted and approved of. It was of a satisfactory nature, notwithstanding the abnormal conditions caused by the war. The president and other office-bearers were re-elected. Mr. Andrew Macfarlane, The Schoolhouse, Auchencairn, was appointed secretary and treasurer in place of the late Mr. G. F. Mills. After consideration, it was agreed to hold the usual show on August 5, 1916. It was resolved that half of the prize money and the full net proceeds of the show should be devoted to the Red Cross or other war relief funds.

ROYAL HORTICULTURAL SOCIETY.

THE fortnightly meeting held on the 9th inst. was certainly one of the smallest of the present season, albeit there were exhibits of importance. For example, the well-grown vegetables staged by Mr. A. Dawkins and the superb grouping of Chrysanthemums from Messrs. H. J. Jones, Lewisham, were of more than ordinary merit. Shrub groups, Nerines, Carnations and a handsome lot of winter-flowering Begonias were, among other things well shown. Orchid exhibits were smaller than usual, and but few novelties were on view.

FRUIT AND VEGETABLE COMMITTEE.

Present: J. Cheal, Esq. (chairman), and Messrs. G. Bates, E. Beckett, A. W. Metcalfe, H. J. Wright, J. G. Weston, A. Bullock, E. A. Bunyard, J. Jaques and Owen Thomas.

Mr. A. Dawkins, 408, King's Road, Chelsea, staged an exhibit of high-class vegetables immediately at the left of the entrance, the collection, while of a comprehensive character, being also admirably displayed. From a background of superb Leeks, Celery, Kale, Savoy and Cauliflower there appeared a collection of nearly six dozen varieties the finest produce of the outdoor garden, not a little interest centring in the fact that many were from July-sown seeds. Of such, indeed, were Model and other Carrots, than which finer produce is not necessary. Intermediate Beet, a selection from the Globe variety, is full of promise, while the Non-Bleeding Beet, as a novelty, will be welcomed by many who have experienced the drawback of broken roots of this useful vegetable. Kohl Rabi was here in high excellence, and we wonder why so excellent a substitute for the Turnip, and one so easily cultivated, is not more generally grown. Rosette Colewort is valuable, too, and worthy of more attention. Walcheren Cauliflower from an April sowing was of model size, and Celeriac, among others, was worthily presented. In addition, Red Globe and Ailsa Craig Onions, Lyon Leeks, Matchless Carrot, as fine and shapely as could be desired; and Ulm Savory, one of the most compact-hearted, were all worthy of remark. Tomatoes, Capsicums, Radishes and saladings were freely shown. Radish China Rose is strongly recommended by the exhibitor as a useful addition. It is of large size and requires good cultivation. Gold Medal.

Mr. Walter C. Voss, Rayleigh, Essex, exhibited a capital table of fruit, chiefly of Apples and Pears, though a particularly good basket of Quinces was also staged. Of the Apples, Lord Suffield, Emperor Alexander, Newton Wonder, The Queen, Lane's Prince Albert, Garret Pippin (a small, yellow skinned variety), Court Pendu Plat and Scarlet Pearmain were all excellent and clean looking. Of Pears, the more notable were Pitmaston Duchess, Beurré Hardy (both very fine), Beurré Bachelier, Durondean and Beurré Diel.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. E. A. Bowles, R. C. Notcutt, W. J. Bean, J. Green, G. Reuthe, J. W. Moorman, W. Howe, J. Jennings, J. F. McLeod, C. R. Fielder, J. Dickson, C. Dixon, H. J. Jones, A. Turner, C. E. Pearson, C. E. Shea, W. P. Thomson, J. T. Bennett-Poë, E. H. Jenkins, W. G. Baker and George Paul.

Messrs. H. J. Jones, Limited, Lewisham, S.E., arranged exhibition and decorative Chrysanthemums in their own inimitable way, the group, while a study in good taste, harmony and contrast, also demonstrating the value of these autumn flowers when employed in imposing stands and vases. In these directions, and with high-class material at their disposal, the firm arranged one of those imposing exhibits for which for years they have been famous. Gold and crimson, with occasional vases of snow white, predominated, not a few of the vases containing a dozen or more of the finest exhibition varieties. In the back row were seen such as Mrs. Edwards (white), Estelle (crimson), Mrs. R. C. Pulling (golden yellow), Seddie Mason (single crimson), Bob Pulling (golden), Wiseman and Willie Westlake, pink incurved and golden yellow pompon respectively. Mrs. H. J. Jones (greenish yellow), Maude Lousada (mauve), Mrs. T. Barnes (single crimson), Buttercup (single yellow), Florrie King (pink single), Mrs. MacNeice (mauve), and Excelsior (bronze single) were other good varieties in a group which for high excellence, superb quality and good arrangement has rarely been equalled and probably never excelled.

Messrs. Piper, Barnes and Bayswater, showed an interesting variety of shrubs and conifers in pots, of which the recently introduced Berberis Wilsonae, B. acuminata, B. dictyophylla (in the way of B. Thunbergii, but with whitish stems), and B. Gagnepanii, were among the more important. Hex Perynii, Tricuspidaria lanceolata, Perpetuas, Juniperus tamariscifolia aurea and Berberis Bealii were also on view.

Mr. J. J. Kettle, Corfe Mullen, near Wimborne, again showed a superb lot of Sweet Violets, of which La France, Princess of Wales, Mrs. J. J. Astor, Ascania, Mrs. J. J. Kettle (very sweet), Marie Louise, and semperflorens (of erect carriage) were among the best in a delightful lot.

Mr. G. Reuthe, Keston, Kent, showed cut shrubs, together with Nerines and other things. In addition, there were pretty pots of Crocuses, C. longifolius, C. ochroleucus, and C. marathonsius (white). An extensive collection of alpinas, chiefly of the choicest Saxifragas, was also on view. Growths of Decaisnea Fargesii, carrying many of the roundish-podded, purple-coloured fruits 4 inches or so in length, were among the more interesting things in this group.

The Misses Hopkins, Shepperton-on-Thames, showed a small collection of alpinas, together with Gazanias and Kniphofias nicely in flower.

Messrs. R. F. Felton and Sons, Hanover Square, exhibited vases and baskets of Solanum ciliatum and Eucalyptus globulus, the pods of the latter of a more glaucous blue and white than is usually seen. With a background of Palms and associated with Scarlet Oak and other foliage, the exhibit was attractive in the extreme.

Messrs. J. Cheal and Sons, Crawley, exhibited a table of cut shrubs to show the effects of autumn colouring. Of these, Acer Ozakasuka, Berberis Thunbergii, Taxodium distichum and Quercus palustris were very good. Euonymus europaeus, Berberis Wilsonae and Cotoneaster frigidula, with masses of scarlet fruits, were all good and distinct.

Messrs. Allwood Brothers, Hayward's Heath, again showed a representative collection of Carnations, such as Rosalind (fancy), Champion (scarlet), Salmon Enchantress, Fairmount (the best of the heliotrope set), The Major (Indian red tone, quite a novel colour), Mary Allwood, and Brilliant (a misnomer in view of its dull crimson and murky white tones. It is, however, quite new and distinct). Yellowstone was also pleasing.

Messrs. W. Wells and Co., Merstham, showed a few novelties in Chrysanthemums, the best of which will be given in "New and Rare Plants" in the issue for next week. Of others, Douglas Wells (a fine yellow incurved) and Mrs. M. Sargent (also incurved) were remarkable.

Messrs. H. B. May and Sons, Edmonton, contributed a table of Ferns comprising hardy Polypodiums, Scolopendrium and Osmundas, among others. Of the former, P. vulgare cambricum Barrowii, P. v. c. Prestonii, P. v. trihomanioides, P. v. cornubiense and P. v. pulcherrimum were the best. Scolopendrium were represented by S. vulgare crispum grande and by others of the ramocristato set, of which S. v. ramo-marginatum and S. v. ramo-cristatum gracile were among the more distinct. Nephrolepis and others were in great variety and beauty.

Messrs. G. and A. Clark, Limited, Dover, showed the new pink Chrysanthemum Pink Favourite, which is of quite an attractive shade of colour.

Pot-grown examples of Solanum ciliatum were shown by Mr. R. Leach, Wood Hall, Dulwich. The seeds were sown in March, the examples well fruited.

Messrs. Stuart Low and Co., Enfield, had a nice display of Carnations, the pick of the group being White Wonder, Alice (the new pink), Lady Fuller (deep pink), and Pink Sensation. This firm also exhibited a table of winter-flowering Begonias, of which Emita (deep orange), Exquisite (rose pink and white), Mrs. Heal, Elatior and Optima were the chief. They were well shown in handsome groups.

Messrs. Godfrey and Son, Exmouth, Devon, showed a table of single Chrysanthemums, all of which, save two, were raised by them. Not all the varieties were named. Captivation and Fascination (both of bronze tone), Devonshire Lass (golden), Crimson Beauty and Golden Utility were very good.

ORCHID COMMITTEE.

Present: J. Gurney Fowler, Esq. (chairman), Sir Harry J. Veitch and Messrs. J. O'Brien, J. Wilson Potter, R. A. Rolfe, R. Thwaites, F. J. Hanbury, Pantia Ralli, F. M. Ogilvie, T. Armstrong, Walter Cobb, J. Cypher, W. H. Hatcher, W. P. Bound, C. H. Curtis, Arthur Dye, W. H. White, S. W. Flory and Gurney Wilson.

Messrs. Charlesworth and Co., Hayward's Heath, had the beautiful Sophro-Catt-Lælia Pandora, whose orange red sepals and crimson lip render it an attraction. Cattleya Phrygia, Odontoglossum armainvillierensis xanthotes, Lælia-Cattleya Prospero, Lælia-Cattleya Golden Oriole, and Brasso-Cattleya Thorntonii (palest mauve sepals and golden-flushed tube, the lip heavily fringed) were also good.

Messrs. Stuart Low and Co., Jarvisbrook, Sussex, showed a great variety of Cattleyas, of which C. labiata alba, C. alba Miss Williams (a very fine form) and C. Alcimedea (another beautiful white) were very good. Sophro-Cattleya Doris (of rich scarlet orange tone) was also shown, with Vanda cærulea and some choice Oncidiums.

From Messrs. Sander and Son, St. Albans, came Cattleya Enid var. Albion, C. alba Princess Royal, Odontoglossum macnabianum (yellow with dark markings), O. Alnum (of rich dark colouring) and Cypripedium leucanum Gratixie, together with many choice Cattleyas.

Messrs. J. and A. McBean, Cocksbridge, Sussex, showed Sophro-Cattleya Pearl, a unique bigeneric hybrid that gained an award of merit; also Cattleya Fabia and Cattleya hardyana.

A bright and interesting group of Orchids in season was sent by Messrs. J. Cypher and Sons, Cheltenham. We observed Cattleya bowringiana atrosanguineum, with masses of bloom; Cypripedium Maudiae and Dendrobium Phalaenopsis splendens in this fine collection.

WARGRAVE GARDENERS' ASSOCIATION.

THE meeting on Wednesday evening, November 3, took the form of competitions in vase decoration. In the class for head-gardeners and foremen there were eight entries, and the following were the prize-winners: First, Mr. F. Gray; second, Mr. H. Attlesley; third, Mr. J. Wixon; fourth, Mr. F. Hobbs. The judges awarded Mr. T. H. Pritchard a second prize in the journeyman's class. The judges complimented the prize-winners on the arrangement of the flowers, some of which were very tastefully staged. Votes of thanks were accorded the judges and the donors of the flowers. A cultural certificate was awarded Mr. R. Doe for a beautiful Lælia-Cattleya. The flowers were despatched to the Reading Hospital the following morning.

THE GARDEN.

No. 2296.—VOL. LXXIX.

NOVEMBER 20, 1915.

NOTES OF THE WEEK.

Chrysanthemums at Finsbury Park.—There is an admirable show of Chrysanthemums in this North London park, and for the next few weeks the house in which they are displayed will be open to the public. The large yellow heads of Bob Pulling appear even more shaggy than usual alongside the delicate pink and finely petalled Rayonnante. Of the large Japanese varieties, D. B. Crane (golden yellow), Mrs. R. A. Witty (reddish terra-cotta, broad drooping florets), Mrs. J. B. Riding (sulphur yellow), Walter Jinks (rose pink) and Queen Mary (pure white, a gigantic beauty) are well represented.

The Golden - Flowered Pericome caudata.—What a pity this beautiful plant is not better known. The strong-scented, golden yellow flowers are produced for a long period at this time of the year. It is a native of Colorado, and was introduced in 1896. By some authorities it is spoken of as a shrub, but in the Botanic Garden, Cambridge, where a large clump growing in the open flowers freely every year, it never attempts to be anything other than herbaceous.

Nymphæas Flowering Outside in November.—It is interesting to see several Water Lilies which are not hardy flowering outside at Kew when the hardy hybrid varieties are over. The pond where they are growing in the Southern Pinetum is slightly heated with condensed steam and surplus water from the engine which maintains the supply of water for the Gardens. Nymphæa Lotus rosea, a beautiful rose, and William Stone, a rich blue, are the very last to flower. These and several other tender sorts add considerably to the interest and beauty of a Lily pond. They are distinct in colour, especially the blue, from the hardy Water Lilies, and the flowers stand 1 foot to 1½ feet out of the water. The tubers are found to keep quite well in this pond during the winter, but they start into growth late, and for this reason are transferred to a greenhouse tank, being returned to the outside pond when the first flowers are opening early in June.

A Rare Orchid from the Philippines.—Vanda luzonica, which gained an award of merit at the Royal Horticultural Society's meeting on November 9, was referred to in the *Orchid Review* last May. Mr. Rolfe, to whom we are indebted for the illustration, says: "We have known this

species for years, but are not aware that any description has been published. Dried specimens, drawings and a photograph were sent to Kew by Mr. Loher in 1906, with the remark that it is allied to *V. tricolor*. The habit and floral structure are well shown in the photograph. The flowers are described as cream coloured, with the front lobe of the lip amethyst. It was found at Montalban, in the Island of Luzon, and living plants were sent

He is the eldest son of the late Mr. Martin John Sutton and eldest grandson of the late Mr. Martin Hope Sutton. He was educated at Harrow and Christ Church, Oxford, and shortly after coming down from the University, in the autumn of 1895, he made a nine months' tour of South Africa, Australia, New Zealand, Tasmania and Ceylon. Subsequently, in the spring of 1897, he became a partner of the firm of Sutton and Sons, and has since

directed his firm's extensive foreign trade.

A Chinese Honeysuckle.—*Lonicera trichosantha* and *L. ovalis* are names given to a Chinese Honeysuckle now fruiting freely in our gardens. Though first discovered by a Russian collector, we are indebted to Mr. E. H. Wilson for the introduction of the plants which suggest the writing of this note. Free in growth, *L. trichosantha* forms an elegant deciduous bush, which is already some 6 feet in height. A pleasing semi-pendent habit of the secondary branches gives this Chinese Honeysuckle a decidedly ornamental appearance. The flowers are yellow, not large, being only half an inch or rather more in length, but they are freely produced, while at the present time the Red Currant-like fruits claim attention. These are borne in the axils of the leaves and usually in pairs, thus appearing in clusters of four.

An Example Worth Following.—In these days, when men of all classes are seeking the best investment, it will interest many to hear that there is at least one man—a keen amateur to wit—whose rate of interest, the result of a small plunge last March, is calculated to make even the most astute financier green with envy. At the period named this grower purchased a sixpenny packet of Rousham Park Onion seed, a selection which would have done credit to a more experienced grower. This he sowed on land having nothing beyond the ordinary digging and manuring one usually associates with the cottager. The drills were 8 inches

apart, and the advice to sow thinly was rigidly adhered to, yet, notwithstanding this, overcrowding was apparent in many places, affording a plentitude of salad for the grower and his neighbours. Three good dressings of soot were given from May to the end of July. The crop was "roped" during the last week in September; this amounted to over three bushels, for which a local greengrocer gladly paid half a sovereign.

VANDA LUZONICA, A RARE ORCHID FROM THE PHILIPPINES, WHICH RECENTLY GAINED AN AWARD OF MERIT.

to Erlangen." The plant shown does not quite agree with this colour description, as the flowers were of the purest white with a crimson purple tipped lip. Such colour variations are not unusual, but the flowering of this species in this country is a matter of real interest to orchidologists.

Mr. Martin H. F. Sutton, J.P.—Congratulations to Mr. Martin H. F. Sutton, who has just been appointed a magistrate of the Borough of Reading.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Rose Earl of Warwick.—Being keen on Rose-growing, I find THE GARDEN much the most interesting of all the gardening papers. Your lists of different Roses with their particular merits and otherwise are most interesting. My experience of Earl of Warwick is quite different from that of your correspondent Mr. E. Waters in his "Roses in Yorkshire." I am only eighteen miles from Leeds, and have only one tree of Earl of Warwick, but it has bloomed so splendidly and continuously that I have ordered a further supply. But I am out of the smoke, which may account for it.—J. V. H., *Scissett Vicarage, Huddersfield.*

Cassia corymbosa Flowering Outdoors.—Almost every horticulturist is familiar with this name when associated with plants for the greenhouse, where it may frequently be found used as a roof plant either planted out or grown in pots, and for many the latter method is preferable, as the growth is not so rampant and may be restricted to the rafters, so keeping the roof glass free. Appreciated as it is inside, I think it is more so when growing out of doors. Here at Fota Island, the seat of Lord and Lady Barrymore, there is a fine plant covering a wall some 24 feet long, and it has been a mass of flower for weeks past. At the time of writing (November 8) it is still flowering freely, and promises to continue so for some time, as there are a wealth of flower-buds unopened. (We have had two slight frosts sufficient to injure Vegetable Marrows.) All through September it was a mass of bloom, and the rich yellow flowers make the plant unmistakable. Doubtless in other parts of Ireland that enjoy a good climate such as this other

good specimens are to be found, as well as on favoured walls elsewhere. It is interesting to note that, according to the "Kew Hand List," it is a native of Tropical America.—E. B., *Queenstown.*

The Fruits of the Strawberry Tree.

I have in my garden two large Strawberry Trees (*Arbutus Unedo*), each bearing at the present time a fair sprinkling of the Strawberry-like fruits. Although bright in colour, the fruits are very poor in flavour. Even birds—which are capable judges of flavour in soft fruits—seem to carefully avoid the *Arbutus* berries unless very short of food in hard winters. It is no unusual thing for the berries to ripen and fall to the ground untouched by birds. Although very little can be said in favour of the edible qualities of the fruit, yet it should be even more extensively grown than it is, by virtue of the fact that it is one of the most beautiful of evergreen trees. The naturally peeled boles of this tree in large specimens are very handsome, and are as much admired as the attractive flowers and fruits. I believe that in Northern gardens this tree is sometimes injured by severe frosts, but here in the South the trees are seldom, if ever, touched by the frost. As a specimen tree for a lawn, *Arbutus Unedo* is much to be commended.—*ARBUTUS, Surrey.*

Deutzia Vilmorinæ in Ireland.

Many people consider this the best of the *Deutzias* introduced to our gardens during recent years. It seems to be seldom damaged by spring frosts, and is proving itself a very free flowering shrub. It reaches a height of from 6 feet to 7 feet, the rather long lanceolate leaves closely resembling those borne by the *Philadelphus*. Its flowering season is usually early June, and at that time its graceful pendent shoots are liberally bedecked with snow white flowers. The flowers are carried in clusters, each being almost an inch across, the petals being prettily crimped. *D. Vilmorinæ* is a native of Szechuan, China, whence seeds were sent to M. Maurice de Vilmorin at Les Barres by the Abbé Farges in 1897. It first flowered in this country about ten years ago.—S. R.

Erigeron philadelphicus.—The illustration of *Erigeron mucronatus*, issue November 6, page 541, calls to mind another pretty form, as above. This charming little plant I found growing in a cottage garden many years ago, since when I have never been without it. It is no trouble whatever to grow. It does not ever require propagating, as seedlings

A FRUITING SPRAY OF THE STRAWBERRY TREE (*ARBUTUS UNEDO*.)

spring up every season, which provide all the necessary stock. Personally, I grow it in the border, but its dwarf habit makes it suitable for any position, as it is constantly sending up fresh sprays of dainty little pink Daisy-like flowers.—T. A. W.

Changing the Botanical Names of Plants.

In reference to the further note on this subject by Mr. W. R. Dykes, I, being but a plain gardener, know nothing of the Vienna Congress. What I do know, however, is that this continual chopping and changing of names is a great nuisance to everyone. It is not as if all authorities were agreed, as the name would then have to be learnt only once; but as it is at present the average individual with but a limited library cannot keep touch with the changes. My original note referred to the general reversal of the names of Ferns, and a good illustration of the inconsistency of the whole affair is to be found in THE GARDEN for November 6, the same number, by the way, in which the last letter from Mr. W. R. Dykes appears. It is recorded on page 543 that *Scolopendrium vulgare crispum speciosum* was awarded a first-class certificate at the meeting of the Royal Horticultural Society held on October 26. As this award was made by the floral committee, and presumably confirmed by the Council, it would appear that both of these bodies countenance the use of false names, for, according to the "List of Certificated Plants," and using the words of that publication, "*Nephrodium* now becomes *Dryopteris* and *Scolopendrium Phyllitis*." As this system of nomenclature has been ignored by both the floral committee and, presumably, by the Council, one cannot avoid asking the question whether such a radical change has been tried and found wanting, or whether these bodies, being composed of practical men, are convinced that the adoption of it will lead to no end of confusion? Other instances of differences of opinion may be found, for in the "Horticultural List" *Richardia Pentlandii* is referred to *R. angustiloba*, whereas in the recently published "Kew Hand List of Tender Monocotyledons" the two are kept distinct. The "List of Certificated Plants" gives the hardy *Clerodendron trichotomum* as a variety of the tropical *C. Thomsonæ*, a climbing plant. I at first looked upon this as a simple mistake, but in view of the upsetting of all preconceived notions, it is now at least open to doubt what is intended.—H. P.

DEUTZIA VILMORINÆ IN THE BOTANIC GARDENS, GLASNEVIN.

Fragrant Roses.—I am much obliged to "E. M." for his supplementary list, issue November 6, page 540, of fragrant Roses, the first-mentioned of which, Queen of Fragrance, I have added within the last week to my collection. In this exquisite direction I think that such varieties as La France, Viscountess Folkestone, and, above all, General Macarthur will not soon be superseded.—DAVID R. WILLIAMSON.

Bracken Roots.—Will anyone tell me where, how, and at what price I can get some bushels of Bracken roots? I want to plant some amid my little "pocket Bournemouth" plantation of Pines and Firs. I read that in some places in Scotland Bracken is considered a pest, and ploughed up and destroyed. Here I prize it as a choice vegetable in spring, a beautiful foliage plant in summer and autumn, and a most useful "litter" whereon to store Apples and to protect tender Roses and perennials in winter.—ANNE AMATEUR.

Apple Lane's Prince Albert.—Is this our most consistent cropper among the indispensable culinary Apples? A really good harvest of them during three successive seasons here almost compels me to that conclusion, at any rate where a poor Apple soil has to be grappled with. The soil here is very sandy, and some fruits do not take kindly to it; but the Apple in question does not heed the compost at all. The trees are in several forms and ages, but they all respond equally well, and the fruit keeps well also. This season they are fit for picking just about a fortnight before last year, which I take it is due to the wonderful September sunshine we have experienced and hardly any rain. — H. TURNER, *Scribby Gardens*.

Two Climbing Actinidias.—The beautiful climber *Actinidia chinensis* made rapid growth this season, the young shoots and leaves being objects of great interest with their covering of bright red hairs. *A. chinensis* is practically a new species from China, and anyone thinking of planting climbers would be well advised to include it in their list. It has proved wonderfully hardy with us here, growing in a very cold, stiff clay. Unfortunately, it has never yet flowered with us, but I understand the flowers are borne in clusters of yellow, succeeded by fruit which is edible and not unlike the Gooseberry. *A. polygama* is another useful species. It is a native of Japan, and differs a good deal in appearance from *A. chinensis*, the leaves in this instance being smooth, with red stalks. Both are rampant climbers. I wonder if any of your readers in the North have ever seen them flower or fruit.—JAMES McGRAN, *The Gardens, Coodham, Kilmarnock*.

The Fruiting of Choice Shrubs.—Your note in the issue of October 16, page 503, on the fruiting of choice shrubs, is very interesting. I have this day (October 16) gathered two dozen fruits of *Magnolia parviflora* containing ripe seeds. The fruits are deep rose coloured, and as they split open reveal bright orange-coloured seeds. I have never seen a *Magnolia* fruit before, and should like to know if it is unusual. I also gathered two fruits of *Xanthoceras sorbifolia*, each containing three fully matured seeds.—A. GRANT, *New Place Gardens, Haslemere*. [*Magnolias* of various kinds produce fruit regularly in this country, and in many cases they are very attractive. *M. tripetala* bears red, cylindrical fruits 3 inches to 4 inches long and 2 inches wide, which, when ripe, split open and release the orange scarlet seeds, each of which hangs from the fruit by a slender, silk-like thread for several days

previous to falling to the ground. This is a peculiarity of the seeds of other *Magnolias* also. *M. conspicua*, *M. obovata* and *M. soulangeana* are other kinds that bear attractive fruit fairly regularly. Perhaps the most beautiful of all the *Magnolia* fruits are those of *M. hypoleuca*, however, for in this case they are a particularly rich red, 4 inches to 6 inches long, and erect on the branches. *M. parviflora* has borne fruit on numerous occasions in this country, from which plants have been raised. The fruiting of *Xanthoceras sorbifolia* is less common.—ED.]

The "Daffodil Year Book, 1915."—While agreeing with Mr. Engleheart's general appreciation of this work and with his congratulations to the Editor thereon, I think it is desirable to put in evidence views of "the other side" on the two matters Mr. Engleheart concentrates his criticism on, and I hope I may be able "to write English" in doing so. It is somewhat of a coincidence (and shows how sadly I fall short of perfection) that in writing to the Editor and to another

and if that is so, why should not we have coloured photographs, even if we have to pay twice or four times as much for our "Daffodil Year Book"? But if we cannot have coloured photographs, I trust we may still continue to have photographs of the novelties, even if it is at the sacrifice of some of the personal portraits. When a man who has been a well-known worker among our favourite flower has to pass away, I think a portrait of him at the midday of his work absolutely appropriate to a Year Book; but while I have the pleasure of seeing him from time to time I do not want his portrait. Would Mr. Engleheart relinquish his desire for portraits if the giving of them up helped, by way of saving money, to our having colour photographs?

The second criticism of Mr. Engleheart with which I do not entirely agree is the one in regard to the tabulated lists of crosses, "successful and unsuccessful." I agree that because a certain flower we have endeavoured to fertilise with pollen from the brush gives seed it does not

COOKING APPLE LANE'S PRINCE ALBERT. IS THIS OUR MOST CONSISTENT CROPPER?

Daffodil enthusiast in praise and criticism of the "Daffodil Year Book," I said I thought more illustrations of flowers and fewer personal portraits would have been better. Uncoloured photographs cannot, of course, convey the general colour effect of a flower, and as an admirer of *Ixion* I particularly noticed the illustration of this flower; but surely a photograph, if honestly taken, depicts the general style of the flower and with more accuracy than many drawings do, as the temptation to make the illustration show up as a picture so often spoils it as an accurate depiction of the flower.

Again, surely the photograph is an invaluable ally to "the power of turning the pen into a colour brush." How greatly Mr. G. L. Wilson's article is illuminated by the photograph of the two dissimilar flowers from one cross! But are colour photographs "over expensive"? When I have been tempted to make enquiries as to the price of coloured photographs of single flowers, it seemed to me that if a number of reproductions were required, the cost would not be "over expensive,"

follow that the fertilisation by the brush produces the seed, but so far as my own 1,700 "successful" crosses are concerned, in very few cases have the results shown that the brush fertilisation has clearly failed and that the flower has been otherwise fertilised.

If the large majority of brush fertilised flowers give progeny, showing the cross has been successful, is it not interesting (especially to the beginner, and, after all, is he not the one to consider most) to know what others are doing and what flowers they have found to give seeds and what flowers have not? Take, for instance, Dr. Lower's unsuccessful crosses; in many instances they confirm my own experience. Possibly it is the unsuccessful crosses that are most interesting or instructive. Always assuming that my suggestion that most flowers after treatment with the brush, if they give seeds have been fertilised by pollen from the brush, is it not most interesting to see what others have succeeded with when we have failed?—C. LEMESLE ADAMS, *Pendeford Hall, Wolverhampton*.

OUTDOOR OR BORDER CHRYSANTHEMUMS.

AVON," on page 545, issue November 6, refers to a variety named Pink Pearl, but, assuming there is a border variety of this name, it will be necessary when ordering to stipulate this fact. The only Pink Pearl I am acquainted with is a variety of the market decorative type. When disbudded it comes as large as Cranfordia, and flowers as late or later, so much so that it runs a great risk of being damaged by frost before opening. It is, however, a most beautiful variety and well worth protection.

In a normal season most of the varieties mentioned by "Avon" are September flowering. The present season, however, is an exception, for with me only Roi des Blancs flowered before October was in. While I admire and grow the small-flowered spray varieties, I would urge everyone to take up the large-flowered market varieties, such as Cranfordia, Cranford Pink, Elsie Eadie, Cranford Yellow, Mrs. Roots, and Framfield Early White. Grown well and disbudded to one on a stem, the flowers are magnificent in October.

Many labour under the impression that large flowers can only be grown under glass, but with such varieties it is easy to get plants carrying six to nine flowers measuring 5 inches or more across. At the time of writing (November 8) Cranfordia is, despite the recent frost, giving grand flowers. To ensure them coming in as early as possible, such varieties should be cut back once only in June and every shoot secured, all of which should be restricted to one flower. They make very good sprays, however, but are somewhat stiff.

For sprays of high quality I favour *Almirante (bronzy red), *A. Barham, *Batchelor's White, *Countess, *Polly, *Crimson Polly, Dorothy Ashley, Dolores, Goacher's, *Mme. Drouard, *Mme. Marques, Nina Blick, *La Neva, *Le Cygne, *Roi des Blancs, and Wells' Crimson.

Nearly all are suitable for disbudding, especially those marked with an asterisk. I would urge everyone to adopt disbudding in the garden, for while it naturally reduces the crop, the quality is so far in advance that the flowers invariably arouse astonishment among those familiar with border Chrysanthemums.

After all, do we not garden largely with a view to showing our friends what we can do? "Grow something different and something better than is visible anywhere about" is the motto I like to act up to. I do not say I always succeed, but so long as I keep up a display differing from the other gardens around I am content. T. A. W.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Odontoglossum Pemburyi (*O. gandavensis* × *O. eximium*).—A remarkably distinct and beautiful hybrid, and one of the darkest-coloured *Odontoglossums* we have seen. The sepals and petals, save for a fine wire edge of white and white tips, are wholly coloured dark maroon, the striking contrast thus created being emphasised by the wholly pure white lip. A robust example was shown bearing a raceme of ten handsome flowers. Exhibited by J. Gurney Fowler, Esq., Brackenhurst, Pembury, Kent.

AWARDS OF MERIT.

Vanda luzonica.—An entirely new species from the Philippine Islands. The exhibited

closely set lip being of crimson hue. From Messrs. J. and A. McBean, Cooksbridge.

Brasso-Cattleya Admiral Jellicoe Broadlands Variety.—A variety of handsome proportions, the sepals and petals coloured rose pink. The frilled lip is of a somewhat deeper shade, and with a touch of yellow in the tube. From Mr. E. R. Ashton, Camden Park, Tunbridge Wells.

Begonia Fireflame.—A good addition to the winter-flowering set, having orange, scarlet-suffused flowers. The plant is of compact habit, very free flowering and sturdy withal. Shown by Messrs. Stuart Low and Co., Enfield.

Chrysanthemum Phyllis Cooper.—Without doubt the finest single variety to date of its colour, which is rich orange yellow. Of large size, with good self-supporting stems and short, stiff neck, it will prove invaluable for decorations. It leaves Buttercup, one of the best hitherto, a long way behind. From Mr. Philip Ladds, Swanley.

Chrysanthemum Golden Champion.—A Japanese exhibition variety of massive proportions and rich yellow colour.

Chrysanthemum Edith Cavell. This is also an exhibition variety with some slight inclination to incurve. The colour is bronzy red, with gold reverse. These were shown by Messrs. W. Wells and Co., Limited, Merstham.

Solanum ciliatum.—A large exhibit of cut fruiting sprays of this species was on view, the numbers of scarlet fruits, the size of a small Tangerine Orange for the most part, creating a great attraction. It is quite a remarkable plant in decoration, lasting for months in good condition. We believe the Kew authorities now refer to it as *S. aculeatissimum*. Exhibited by Messrs. R. F. Felton and Sons, Hanover Square, W.

NEW FRUIT.

Apple Madresfield Court (Ribston Pippin × Worcester Pearmain).—An attractive-looking dessert sort of conical build and moderate size. The flesh is slightly yellow, soft and juicy. From the flavour standpoint we regard it as a second-rate variety. From Mr. J. Carloss, Melbourne, St. Barbourne, Worcester.

The whole of the foregoing novelties were exhibited before the Royal Horticultural Society on November 9, when the awards were made.

THE AUTUMN CROCUSES.

From the aesthetic point of view, there is little doubt that *C. speciosus* and its varieties take first place among the autumn Crocuses.

C. s. Aitchisonii is considerably larger than the type, if a trifle paler, and *C. s. Artabir* eclipses both the foregoing and is altogether a most desirable Crocus. *C. s. albus* is quite unique, of

NEW SINGLE YELLOW CHRYSANTHEMUM PHYLLIS COOPER.

example, which bore a short raceme of five or six flowers, is believed to be unique. The flowers are of the purest white, with crimson purple tipped lip. It is as beautiful as it is distinct. Shown by Messrs. Sander and Sons, St. Albans. (See illustration and note on "Notes of the Week" page.)

Sophro-Cattleya Pearl (*Sophro-Cattleya Doris* × *Cattleya Portia magnifica*).—A distinct and solid-looking variety of somewhat flattish appearance, caused by the lie of the broadly ovate petals, the sepals being quite narrow by proportion. The dominant colour is reddish purple, the sturdy,

course, and its white satiny flowers are very attractive; unlike many albinos, it has a good constitution.

C. nudiflorus, the Naked-flowered Crocus, is also very attractive with its pale bright purple flowers. *C. asturicus* has purple lilac flowers, striped darker towards the base. *C. medius* has deep purple flowers, which show up well in the autumn sun. *C. longiflorus* is a charming Crocus, sweetly fragrant; it has lilac flowers, their beauty enhanced by their red pistil and yellow anthers.

The foregoing selection by no means exhausts the list of autumn Crocuses, but I think they are among the best. They are all quite cheap. Autumn Crocuses should be planted not later than the end of August.

CALEDONIA.

LAPAGERIA ROSEA.

THE Lapageria has now been familiar to us for more than sixty years, having been introduced from Chile in 1847. Notwithstanding this fact, it is surprising to note how comparatively seldom one sees a plant of it flourishing

as a perfectly healthy specimen should do. This is to be deplored, for the Lapageria, unless successfully cultivated, is, perhaps, of all greenhouse plants, the most disappointing. Its culture understood, however, it undoubtedly proves one of the most attractive and useful cool-house climbers we have. The wax-like flowers, gracefully hanging from the roof of, it may be, a corridor, or a small or large conservatory, make a display that for refined beauty would be difficult to surpass.

The genus Lapageria contains only the one species, *L. rosea*, but the flowers of this vary considerably in size and substance, according as one has a good or a bad form of it. It behoves one, therefore, to be careful in selecting one's plants, and to obtain them from a stock that can be relied upon. An excellent way of displaying the flowers of the Lapageria to the best advantage is to plant *L. rosea* and *L. rosea alba* alternately, or, say, two of the former and one of the latter. By adopting this method the beauty of both is enhanced by the contrast produced.

Lapagerias usually succeed best when planted out and disturbed at the roots as little as possible.

When cultivated in pots it, of course, becomes necessary to disturb them at intervals for the purpose of repotting, an operation that is not conducive to their well-being. A fairly large root run will be required, so as to ensure the non-disturbance of the roots for several years at least. The depth of soil need not, indeed must not, be great, or the roots will eventually descend beyond control, perhaps into soil that is unsuitable to them. By having the majority of the roots comparatively near to the surface of the prepared border, when a fresh supply of food becomes necessary this can easily and effectually be supplied by a top-dressing of new and enriched soil. That thorough drainage should be provided for such an amount of soil goes without saying; rough sand and charcoal mixed with the compost of peat and loam will ensure this.

It is important to commence with strong and vigorous plants, preferably obtained by layering firm, healthy shoots. These when well rooted can be taken up and transferred to their permanent quarters at once. Weak plants, even if they do eventually succeed, which is improbable, are for long a source of disappointment.

It would be interesting to hear from readers who have had experience in the outdoor cultivation of Lapagerias—said to be successfully practised in some of the warmer districts of

Britain—if they really grow sufficiently well to be of value in the garden. We have seen Lapagerias growing outside on a warm wall in a Surrey garden. The plants are growing moderately well, and are at this very time producing a few trusses of bloom; but we have never seen Lapagerias really happy in an outdoor position, though it is probable they would succeed in Cornwall.

TWEEDIA CÆRULEA.

By J. T. BENNETT-POE, V.M.H.

It is often a matter for surprise why the subject of this note has been ousted, as so many other good and interesting plants have been, by the craze for many years past for Pelargoniums and Begonias. Blue flowers for the greenhouse are none too many, and this one is of such an exquisite turquoise blue that one wonders why it is not often found in our greenhouses in summer-time, when the long continuance of its blooming season renders it valuable. It is easily grown from seed, is a perennial of slender, semi-climbing habit, and if cut down in the spring when young growth from the base has well started, it soon makes a good plant for the ensuing season. Introduced more than half a century ago, it first flowered at the Glasnevin Botanic Garden, and was figured in the *Botanical Magazine*, t. 3630. It is also found under the name of *Oxypetalum cæruleum*. It is a native of South America.

LAPAGERIA ROSEA, A WELL-KNOWN GREENHOUSE PLANT WITH WAX-LIKE FLOWERS.

GARDENS OF TO-DAY.

MARKYATE CELL, HERTS.

THIS fine old place, in the generous hands of its present owner, William M. Macleod, Esq., has been so wonderfully improved during the last few years that it has become one of the most delightful of English gardens.

Mr. Macleod purchased the estate some five or six years ago, and in that short time has trans-

Coniferae do not thrive very well on the chalk, and none of any size is to be met with.

The Rose Garden.—This is one of the features at Markyate Cell, and has been very carefully planned. The beds are filled with some originality, for instead of, as is usual, each containing one variety, several varieties of nearly the same colour are planted in each. This, besides allowing a much larger number of varieties to be cultivated, also ensures a fine display every year, as when one variety may not find the season entirely to its liking, another invariably does so.

In front of this are large beds of Dwarf Polyantha Roses in all the finest varieties. Very fine were Jessie and Katherine Zeimet. Dotted between these Roses are hybrid Gladioli, which in autumn provide a fine display when the Roses are over. A broad walk runs the whole length of the garden and in front of these Rose-beds. On the opposite side of this walk is quite a unique feature. It consists of three rows of dwarf Tree Box, planted hedge fashion, and with about 12 inches between the rows. At regular intervals and at right angles one row of the same runs out

to the walk. The "bays" thus formed are planted with sweet-scented flowers only, such as Stocks, Lavender, Mignonette, Nepeta and Heliotrope. The Nepeta is largely used all over the garden, its masses of lavender-coloured flowers being very restful to the eye. On the next terrace the sloping bank is filled with oblong masses of all the best Antirrhinums. When in full flower this is quite a brilliant border.

The Pergola.—The next terrace is entirely filled with an imposing pergola and flanking broad herbaceous borders. These borders are filled with great numbers of the best perennials and biennials, besides bulbs, &c., and are thus wonderfully bright from February to November. At the time of my visit, Delphiniums, Gaillardias, Canterbury Bells, Violas, Nepetas, Erigerons, English Irises, Campanulas, Anchusas and many others were in full glory. For late blooming, Phloxes,

Asters, Dahlias, and Helianthus are in large numbers. The pergola itself is rather out of the common, the pillars being of brick. Roses, Honeysuckle, Clematises and other climbers are employed to clothe this structure. The effect is very fine, and will be even better a year or two hence when everything has made more growth. Small square beds filled with *Lilium candidum* and carpeted with Violas surround the bases of the pillars, affording a fine setting to the whole.

The Blue Border.—This is another charming feature of this unique garden. It is not always an easy matter to successfully lay out a one-colour border, but I must say the one under review is well done. The plants used are Anchusa, Erigeron, Delphinium, Lavender, Nepeta and several others. A patch or two of a very fine strain of *Convolvulus minor* has a telling effect in this border.

The Glass Houses.—These are all new structures, and Messrs. Weeks and Co. of Chelsea were just putting the finishing touches to the work. They consist of three span-roofed ranges and are of the latest type, with some quite recent improvements in ventilating gear. The structures are plain, but substantial and thoroughly well

MARKYATE CELL: LOOKING ACROSS THE ROSE GARDEN TO A STEPPED YEW HEDGE.

formed the gardens from an uninteresting wilderness into a perfect and restful floral Paradise. All this improvement, wonderful to relate, has been carried out without changing the old-world charm which is one of its greatest attractions. While Mr. Macleod is passionately fond of his beautiful garden and noble park, it is really his gifted lady who is responsible for the planning of the improvements. In this praiseworthy work she is ably served by her gardener, Mr. J. W. Forsyth, who, besides being an able, all-round gardener, is an excellent draughtsman. Mrs. Macleod, while taking full charge, as it were, of the remodelling of the gardens, leaves the working out of details to her gardener, and this he invariably carries out in a most satisfactory manner.

The Park.—This is of generous proportions and beautifully wooded. Of at least 100 acres in extent, it rises gradually from the public road to the house. It is seldom that I have seen finer park trees. Walnut, Elm, Sycamore, Ash, Oak and Chestnut, all of fine growth, are the principal kinds, and very imposing they are. Chestnuts are of much greater height than is commonly met with and when in flower are very effective.

This year all varieties seemed to have found the season favourable, for on my visit on June 30 the whole garden was a picture of beauty. It would be wearisome to mention the names of all the Roses used, but specially good were Molly Sharman Crawford, Lieutenant Chauré, General Macarthur, Caroline Testout, Mme. Abel Chatenay, Château de Clos Vougeot, Mme. Segond Weber and Pharisæer. A large corner bed is filled with mixed Roses, and these, too, showed up bravely. The wall on the north side of the Rose garden is surmounted by a narrow border and walk, as the ground rises abruptly here. The border is planted thickly with the pretty pink Rose Mrs. Cutbush, and is a very effective and appropriate finish to the garden. The stone-paved paths, with numerous alpenes growing in the joints, make a charming change from the orthodox gravel walks.

The Flower Garden.—This is of considerable extent, and consists of a series of terraces, all beautifully planned and laid out. Starting at the top or north side, we have the original garden wall, against which has recently been planted a number of Peach, Apricot and Plum trees. Some 3 feet or 4 feet from the wall is a dwarf hedge of that pretty pink Rose Zephyrine Drouhin.

finished. The heating is ample and thoroughly under control. Altogether a well-planned glass department.

The Dutch Garden.—This has only recently been completed, and is, in a measure, the finishing touch to the many satisfactory schemes undertaken during the last year or two. This new garden takes the place of what was truly an eyesore when in close proximity to such a well-planned garden. An old sawmill and other necessary but unattractive objects have been removed and this beautiful formal garden substituted. *Preston House Gardens, Linlithgow.* C. BLAIR.

SWEET VIOLETS.

THE fresh, sweet smell of Violets on a warm, dry bank near the house of the writer in Buckinghamshire served as a reminder of the exquisite varieties that are the pride of many an English garden—the large deep blue Princess of Wales, the white Comte de Brazza, each flower a perfect rosette of petals, and the pale-lilac Marie

Louise. A frameful of the Violet Princess of Wales is something to feel proud of, and the long stems make it most acceptable for cutting. It is only in the pure air of the country that the Violet can be grown with any success. Fog, smoke, and the impurities of the town air are an abomination to it, and it is for this reason that attempts to cultivate the plant near large towns have been given up as certain failures. I know of one great garden near London in which no expense has been spared to coax the sweet flower to behave itself, but without success, the winter fogs, dampness and absence of sunlight quickly turning the leaves yellow, which is the first symptom of general decay. The soil should be well prepared, and, if naturally light, should be made heavier by incorporating with it, some time before planting actually takes place, well-decayed manure and leaf-mould. If, however, it is heavy, the manure will not be necessary. A start may be made at the end of March, when the plants may be put out about 2 feet apart in the rows, with a space of 15 inches between the tufts, except in the case of the variety Princess of Wales. This develops in one season into a tuft 18 inches across, and therefore about 3 feet will be the correct

space. Always purchase the strongest plants; they may be more expensive, but the return they will give in flowers will repay for the additional outlay. In February the ground should be prepared in readiness for the plants to go out at the time I have mentioned. During the summer months water freely when the weather is hot and dry, and hoe occasionally between the tufts, for the twofold purpose of keeping down weeds and preventing the soil from becoming, as the gardener says, "caked"—that is, too solid to allow access of rain and air to the roots. Another way of sheltering the plants during a very hot summer is to spread leaf-mould or short manure between them. This not only acts as a protection, but is stimulating to the growth.

Perhaps one enjoys the Violet more in the winter than at any other season of the year. Its fragrance brings thoughts of warmer days to come, and a few flowers of the Princess of Wales variety will scent a large room. Where Violets are desired in winter, the plants should be removed to cold frames or slightly heated glass pits at the end of September; but nothing must be attempted in the way of forcing. The Violet loves the cool fresh air of the wayside bank, and resents an

MARKYATE CELL: CHIEF STAIRWAY LOOKING EASTWARDS.

overdose of artificial warmth by promptly dying. In large gardens Cucumbers and Melons are grown during the summer in pits, and these latter may be made use of for the Violets, adding, if any is required, poor soil to prevent an undue luxuriance of foliage, to the detriment of the flowers. When digging up the Violets from the bed for planting in the frames, a large ball of soil should surround the roots, to minimise as much as possible any check to the progress of the growth. Plant them close together, and remove the lights whenever the weather is warm or showery. The only protection needed is from frost or heavy rains.

I have picked Violet flowers in winter from the permanent bed by protecting it with a framework of wood, 15 inches from the ground. Over

THE PYRACANTHAS.

THE Pyracanthas are bright evergreen shrubs allied to the Cratægus and Cotoneaster families, in which genera they have been included by some botanists. For garden purposes they are distinguished from the Cratægus in being evergreen, and from the Cotoneasters in having thorns on the branches. The Pyracanthas thrive in well-drained garden soils of a light and warm rather than a sticky character. Seeds form a ready method of propagation, and cuttings, made of shoots of the previous summer's growth, root in a cold frame in autumn. Four species and several varieties are in cultivation. They do not transplant readily, and plants should be grown for a year or two in pots, or placed in the permanent positions when small.

Pyracantha angustifolia.—This is essentially an evergreen shrub for a south or west wall, except in the South and West, being the least hardy. In such a position it is, however, a most beautiful shrub, both when freely clothed with corymbs of small white flowers in summer, and throughout the winter when laden with orange yellow fruits. It is very noticeable that the birds leave the fruits of this species hanging when practically all other berry-bearing trees and shrubs are cleared. The species is a native of Western China, and was first introduced in 1899 by Lieutenant Jones. In the *Botanical Magazine*, t. 8345, it is figured as *Cotoneaster angustifolia*.

P. coccinea.—This is the common Pyracantha, a native of South Europe and Asia Minor. It is a very old garden shrub, having been first introduced about 1629. In the open *P. coccinea* forms a large evergreen bush of considerable height, but it is as an evergreen climber that the plant will be familiar to most readers. In early June the long sprays are clothed with corymbs of white flowers, followed in autumn by rich red fruits. The shrub which is such a conspicuous feature on many suburban villas at the present time is the variety *Lalandei*. From *coccinea* it is readily distinguished by the orange red fruits, and is said to fruit more freely. Certainly it would be difficult to crowd more fruits on some of the branches at the present time. The gorgeous colour

of the fruits has evidently caused it to be known by the popular name of the Fire Thorn. Blackbirds and thrushes in some districts clear the bushes so speedily when ripe that in some gardens it is thought worth while to place nets or cotton over them. *Lalandei* is a seedling variety raised about 1874 by M. Lalande of Angers.

When pruning of Pyracanthas is necessary, it should be done in early spring. They stand pruning well, but when cut hard it naturally interferes somewhat with the flowering and fruiting during the coming season.

P. crenulata.—This species was originally introduced from the Temperate Himalayas, and is known as the Nepalese Whitethorn. It is on the borderland of hardiness and, except in the South and West, should have the protection of a south or west wall. The plants are not so vigorous in growth as the other Pyracanthas, and are thorny bushes with white flowers and orange yellow fruits.

HART'S - TONGUE FERNS (SCOLOPENDRIUMS).

BY E. H. JENKINS.

I SUPPOSE there are few indeed who would take exception to the remark that, among hardy Ferns, the Hart's-tongue, as the *Scolopendrium* is commonly called, occupies a place entirely unique. Happy in the cool, moist loam of many a ditch bottom and ornamenting the sides thereof in its own inimitable way, this accommodating Britisher would appear almost as content when the crown of the once tiny sporeling, having reached a more mature stage, is seen oozing out, as it were, from the veriest crevice of almost vertical sandstone rock, colonising there in its dozens or hundreds. True, not every gardener has a ditch bottom, or even vertical sandstone rock at his disposal, and, in truth, they are not essential. They serve to show, however, the part played by certain conditions, *e.g.*, moisture and uniform coolness, the things that really matter in the cultivation of this fine race of Ferns, and which, moreover, are not impossible of imitation.

During recent years, on some of the more elaborately arranged rock garden exhibits these Hart's-tongues have been seen to advantage in the cool recesses of rocky caves, where, sprayed with the drip from above, they have looked their best. Or the hardy fernery, so to speak, has been enacted under trees, the twain suggestive of some of the diverse uses to which these plants may be put. Those who have neither a rock garden nor a hardy fernery in which to grow them may still cultivate the best in pots or pans with quite a full measure of success, as the recent exhibits of Messrs. H. B. May and Sons, Edmonton, and Mr. Amos Perry, Enfield, have demonstrated. Indeed, Fern-lovers owe the specialists named no little debt of gratitude in bringing these plants to the front, and few exhibits attract greater attention. A great charm about the Hart's-tongue not yet mentioned is the cool, refreshing greenery of its fronds, than which nothing is more welcome on a sultry summer's day. It is, however, good at all seasons, though best of all perhaps as the mature stage of the season's growth is reached, and doubly welcome because retained long after the more truly deciduous kinds have completed their year's work.

THREE PYRACANTHAS.

From left to right: *P. angustifolia*, *P. coccinea Lalandei* and *P. crenulata*.

this mats were put, and unless the weather is exceptionally severe, the plants have not refused to flower freely. As to varieties, Princess of Wales is unquestionably the finest of all. Each flower is larger than a shilling and the stems are very long, thus enabling it to be used for table decorations and in other ways. *Wellsiana* is smaller in growth and bloom, but the colouring is very pretty, a blue with a trace of bronzy red. If only one single Violet can be grown, choose Princess of Wales; and of the double varieties, Marie Louise, though some prefer Lady Hume Campbell, which blooms several weeks later. Then there are the double white Comte de Brazza, the Neapolitan and Mrs. Astor, all having the attributes of fragrance and pretty colouring.

Doubtless among the numerous readers of *THE GARDEN* there are not a few who know something of the undying interest of the hardy fernery under glass, and to such the value of the Hart's-tongue Ferns will be well known. To those who have not grown them thus it may be an encouragement to know that without fire-heat and at a minimum of cost and labour they may be grown to perfection in a house with preferably a north or north-westerly aspect, where few flowering plants would succeed owing to lack of sunlight.

Quite one of the most interesting facts in connection with the Hart's-tongue Fern is centred round the wealth of variety which has arisen from a single species, and I have read somewhere that some 400 or more varieties have been described. Modern lists for the most part are, however, content with giving a few dozen sorts, of which the crispum forms are, to my mind, the most handsome. One of these, *Scolopendrium vulgare crispum speciosum* (see illustration) was exhibited before the Royal Horticultural Society on October 26 by Mr. W. B. Cranfield, Enfield Chase, when it was awarded, as it justly merited, a first-class certificate. This magnificent example, some 3 feet across, with fronds probably 2½ feet long, was a great attraction, as much by its imposing character as a whole as the ample Elizabethan-like ruffles which constitutes the margins of the fronds.

A good companion to this is *S. v. c. grande*, recently well shown by Messrs. H. B. May and Sons, and both are great advances—the topmost rung of Perfection's ladder, as it were—on the better-known crispum. *Latifolium Robinson's* variety and *robustum* are other bold and handsome forms of the crispum set. Next to these in point of popularity I should place the crested forms, those of the *cristatum* and *ramo-cristatum* sections more particularly, whose fronds are terminated by a heavy tassel or crest. *Coolingii*, *Kelwayii*, *grandiceps*, *ramo-cristatum* and *corymbiferum* are some of the best marked of these, and as such indispensable to any collection. There are, of course, many others, together with divisions and subdivisions of the group, of which the exigencies of space preclude a mention even by name. Happily, however, the plants retain their characteristics practically throughout the year, and those interested may therefore make a selection at any convenient season.

MY LITTLE GARDEN IN KENSINGTON.

HAVE any of my London readers discovered the autumn Crocus yet? It has burst upon me this year as a revelation. I was induced by some particularly persuasive catalogue to include a hundred in my order for bulbs, and was just in time to plant them, on my return from a summer visit spent in the country, the third week in September—though all the catalogues recommend August planting. And now, as I write, a hundred lovely blue faces smile up at me in the autumn sunshine, having struggled each morning through the fog without losing a particle of their beauty.

blue, shaded buff, stigmata brilliant orange; and so on to the extent of about twenty different kinds. They are reasonably cheap, too, my own blue hundred having cost me but 3s., though they vary in price from that to as much as 18s. a dozen.

Colchicums I have also grown this year in an odd corner near my drawing-room window, and though each bulb did not flower, those that did threw up about six or eight flowers in a clump, which made quite enough show to justify the experiment. These should, like the autumn Crocuses, be put in in August.

Since I am prating of bulbs, I am in danger of becoming boring on the subject of English Iris, which can still be planted, though earlier is best. Who that has a garden does not know the exasperation of a clump of prosperous-looking, vigorous German Iris (other than the common purple one), that yet will only give you a flower when its caprice

permits, which might be only once in some years! It is like having a man next you at dinner whom you know to be full of humour and other delightful characteristics, who yet sits dumb beside you, you not having had the good fortune to strike a note that will let loose his riches. It seems almost too good to be true, then, that you can have hundreds of glowing Irises growing close together with wonderful effect in July, when they give the one necessary touch to a summer border, and for a ridiculously small sum—my own costing 2s. 6d. a hundred, each bulb giving

always two and sometimes three blooms each. Plant these fairly deep in about 3 inches of coarse sand and cover them well up with sand; mulch with a top-dressing of manure to keep them warm in winter, and I can promise that you will be thankful for having taken this trouble—so delicious will be the sheet of all that is most beautiful in blues and mauves and splashes of yellow. The Spanish Irises do less well, every bulb not invariably flowering, but they have the advantage of flowering some ten days earlier than the English Iris. I myself plant them all in the same beds, which then flower continuously from early June to well on into August, giving a maximum of pleasure for a minimum of labour, always an advantage in London, where labour such as this, involving a certain amount of knowledge, must usually be done by one's self.

HELEN F. R. SHARPE.

23, Pembroke Road, Kensington.

A NEW HART'S-TONGUE FERN: *SCOLOPENDRIUM VULGARE CRISPUM SPECIOSUM*.

They are lasting well, and some of the bulbs are putting up a second and third flower. I bought *Crocus speciosus*, since I have not yet outgrown my passion for blue in the garden; but I am now willing to believe other kinds are equally beautiful, and next year there will certainly be as many as my small garden will accommodate. Many of the catalogues have a separate list of autumn-flowering bulbs, a useful idea that saves much searching in garden books in a generally vain attempt to collect details of time of flowering, colour, and time to plant—all details that worry the ignorant, among whom I myself loom large and dense. I see, then, in my pet catalogue that *Crocus cilicicus* is pale blue with yellow tube (the tubes are particularly bright in the autumn Crocus) and veined purple, blooms September; *Crocus hyemalis*, silvery white, striped rich blue black (does it not sound delicious?), blooms winter; *C. Imperati*, violet

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Late Muscat Grapes.—A well-appointed Grape-room is an invaluable asset in private establishments. Those favoured with such a convenience can cut their Grapes any time between this date and the end of the year, and provided they are perfectly ripe they will keep just as well in the Grape-room as if left on the Vines. The Vines can then receive attention in regard to watering. Any renovation or extension to borders can also be attended to. Unless the houses are needed for sheltering plants, they should be thrown wide open, so that the Vines may have a period of absolute rest.

Midseason Vines.—The pruning and cleaning of Vines which are at resting must be persevered with. Young Vines may be pruned to two buds, but in dealing with very old Vines it is prudent to leave three or four buds, or even more. After pruning young Vines, the newly made cut should be painted with styptic as a precaution against bleeding when they are started in the spring. Vines which are infested with mealy bug must be given a thorough cleansing. All loose bark should be carefully removed and the rods thoroughly scrubbed, using a strong mixture of soft soap and sulphur. The vineries may also be fumigated with sulphur. Proceed with the work of extending and renovating borders.

Plants Under Glass.

Richardias.—A few of the strongest plants may be selected and placed in a warm house if they are required to flower early. As a rule, Richardias are not required until the Chrysanthemum season is over. The main batch must be kept in a cool house near to the glass. Fumigate them occasionally to keep them free from aphids.

Chrysanthemums.—When these have finished flowering, cut them down and place the stools near to the glass in a light house. The object now is to procure clean, sturdy cuttings. Carefully go over the stock with a view to discarding useless varieties. Prepare the soil and place it in a heap till the time arrives for inserting the cuttings.

The Flower Garden.

Plants in Cold Frames.—Plants which are to winter in cold frames must be occasionally overhauled. Remove dead and mildewed foliage, and stir the soil between the plants with a pointed stick. Whenever the weather will allow, the frames must be liberally ventilated, or many plants may be lost if this matter is neglected. The plants, too, will suffer during severe frost if they are not thoroughly hardened.

Protecting Tender Plants.—Plants which are known to suffer during times of hard frost must now be protected. A quantity of Bracken and Heather should be put in a dry place in readiness for this purpose. Some substitute for Archangel mats must be found this season. Branches of evergreen, especially those of the Yew, may be made use of to protect many of the less hardy subjects. Ashes or Coconut fibre placed round the base of some of the less hardy herbaceous plants forms an adequate protection.

Christmas Roses.—These are always in favour at Christmas-time, and an effort should be made to have a good quantity of blooms by that date. Place frames over them now, and during times of severe frost put some protecting material over the glass. Keep a sharp look-out for slugs, or many of the flower-buds will be spoilt.

Roads and Paths.—To keep these in good order, a portion of the work of remaking or mending must be attended to every season. Any defects in the drainage must also be made good now. Grass verges must be cut and levelled where this is necessary.

The Hardy Fruit Garden.

Peaches and Nectarines.—In some districts Peaches and Nectarines flourish out of doors, while in others they are quite the reverse. Here, on a chalk subsoil, they have never been a success outdoors. Where they are known to succeed they should be grown largely, as any surplus fruits

may be bottled, and these will be found of great value during the winter months. The present is the most suitable time for planting trees. Have the stations thoroughly prepared before the trees come from the nursery, and lose no time in planting them when they arrive. Examine the roots carefully and cut back those which have been damaged, also those which are too strong. Plant firmly and keep the roots near the surface. Place a mulch of short manure over the rooting area when the planting is finished.

The Kitchen Garden.

Seakale.—When the foliage has died down, a few roots may be placed in the forcing-house. Plant the crowns fairly close together and thoroughly water them in. They are not particular in regard to soil. Old potting soil or that which has been taken from a Melon-house will be suitable. It is necessary to have a little warmth under the roots, which may be provided by a hotbed or hot-water pipes. The crowns must be kept quite dark.

Rhubarb.—A few roots may be placed in heat. Rhubarb may be readily forced in a Mushroom-house or beneath a stage in a house which can be kept warm and moist. If two or three roots are placed in heat every fortnight or three weeks, a good supply will be assured.

Tomatoes.—The winter fruiting plants will now be ripening their fruits, and in order to keep up the supply as long as possible, every attention must be given to cultural details. A dry atmosphere with a constant circulation of air, more or less according to outside conditions, is essential. Some of the foliage may be removed if it tends to obscure light. If there is room for a little fresh soil on the surface of the pots, this should be given to encourage fresh roots. A temperature of 55° to 60° should be maintained.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Flower Garden.

Pæonies.—Where borders or beds are to be planted with Pæonies, the ground should be treated to a very liberal dressing of farmyard manure. As these plants do not like being disturbed frequently, it should be deeply trenched and given a quantity of bone-meal. Should frost delay the planting at this time, try to get them put in at the first opportunity, as they commence emitting roots very early in spring.

Cannas which may have been lifted to make room for spring bedding and heeled in outside to mature their growth must now be brought indoors for protection from frost. They may be partly cut over and placed underneath a cool greenhouse stage, or in some shed which is not too dry or warm, which would excite the plants into premature growth.

Bamboos.—These handsome plants are not hardy in many districts, so that where they are planted out in unfavourable sites temporary protection is necessary during winter and early spring. Wind is usually more harmful to these plants than frost. Where the soil is very wet, which condition suits the Bamboo during summer, the plants are sometimes cut down by 20° of frost. Again, in more sheltered positions—for instance, growing among coniferous trees—they remain unharmed with 25° of frost. Rather than try to cover the actual plants, a screen of evergreen branches should be erected to surround them.

Plants Under Glass.

Azalea indica.—This can now be forced in quantity if required for early work. If placed in a stove where it will receive plenty of moisture from the atmosphere, it comes quickly into bloom. For general purposes the Indian Pearl variety is best. Where a number of plants are grown, those which have become too large or developed too much bare stem should be chosen for this work, leaving the more shapely and better plants to flower in their natural season.

Hyacinths.—The Roman Hyacinths can now be brought quickly into flower when placed in

heat. The Dutch varieties, however, cannot be flowered so early, unless they are the specially prepared bulbs which have been obtainable for the last two seasons. Where these were potted in August, a portion of them may now be placed in heat; but as they can only be had in bloom at their earliest by Christmas, forcing should be gentle.

Tulips.—These are able to withstand more heat than most bulbs when being forced. The greatest difficulty with very early flowers is to get a sufficiently long stem or growth. Such fine varieties as Proserpine and Mon Tresor give beautiful, large blooms but miserably short stems. This trouble can be largely overcome if, when the bulbs are put in heat, a good thick layer of moss is placed over them to induce the stems to lengthen. As growth proceeds more can be added, so long as the foliage and flower-buds are not allowed to bleach.

The Kitchen Garden.

Rhubarb.—In view of possible frost coming, a number of crowns should be dug up and left lying on the surface fully exposed. Roots which have not been subjected to frost do not respond readily to any amount of bottom-heat.

Potatoes.—Seed Potatoes should be examined occasionally to see there are no diseased or decaying tubers allowed to remain which might contaminate others. The tubers which are to be grown for very early supplies in frames or pots should be picked out and arranged in shallow trays, thus allowing them to develop strong sprouts. These tubers can now be placed where they will get slightly more light, but not where the atmosphere is at all warm.

Broccoli.—Where there is danger of injury by frost to any Broccoli which are developing heads, the plants can be lifted with a fair amount of soil attached to the roots and placed in deep frames. This is more necessary in wet districts and where the soil is of a clayey nature.

Broad Beans.—A sowing can now be made for the early crop next year. A border with some protection is best, but the plants are able to stand a reasonable amount of exposure. Where the grower has plenty of available room indoors for raising young plants during early spring, this sowing will not be required at this date, as young, vigorous plants resulting from an early indoor sowing, if planted out in good time, will generally bear as soon as, if not before, those sown outdoors at this season.

Digging and Trenching.—For such a crop as Onions it is of great advantage to prepare the ground beforehand in the early winter, leaving the soil as rough as possible, thus exposing a greater surface to the beneficial influence of frost, rain and snow. A record should be kept of each part of the garden as it is trenched, so that no section is omitted in its turn, which should be every third year at the least.

The Hardy Fruit Garden.

Wall Trees.—Pruning can be commenced on the trees as soon as the leaves have fallen. The trees can then either be nailed up or, if a trellis exists, the previous ties should be looked over to see that all are in sound condition. Such trees as Morello Cherries, which call for more expert training, should be attended to before severe weather arrives, as then it is not an easy matter for the person tying to train the trees as they should be trained.

Fruit Under Glass.

Strawberries in Pots.—To have ripe fruit early in March, a start must be made by placing the plants indoors by the end of the present month. If the crowns are thoroughly ripened and have been exposed to a few degrees of frost, growth will be stronger and early. Where a house or pit cannot be devoted to them, they may be placed on a shelf in an early vinery or Peach-house. Any weeds which may be growing should be removed when the pots are being washed before bringing them indoors. Much water will not be required until January, after growth has fairly started. At the same time, the plants should be looked over frequently, as allowing them to get too dry would be just as injurious.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)
Castlemilk Gardens, Lockerbie, N.B.

LATE-FLOWERING ALPINES.

By Miss Ellen Willmott, V.M.H.

THE interesting lists of alpine now blossoming in various rock gardens inspired me to look round mine to see if it could also have any pretension to gayness in early November.

I noticed the following plants with not only a solitary one or two flowers, but several, and in some instances many: *Viola rothomagensis*, *V. floraiensis* and others, *Saxifraga Fortunei*, *Omphalodes Luciliae* and *O. nitida*, *Geum Borisii*, *G. chilense*, *Sedum Sieboldii*, *S. ternatum*, *S. turkestanicum*, *Liatrix spicata*, *Zauschneria californica*, *Erigeron mucronatus*, *Saponaria ocymoides*, *Campanula garganica*, *C. portenschlagiana*, *C. Stansfieldi*, *Erodium Manescavi*, *E. olympicum*, *E. willkomianum*, *Lychnis Lagascae*, *Phlox G. F. Wilson*, *Satureia pygmaea*, *S. montana*, *Convolvulus sabatius*, *C. cantabricus*, *C. lunoides*, *Verbena venosa*, *V. chamaedrifolia*, *Dianthus croaticus*, *D. gallicus*, *D. inodorum*, *D. aridus*, *D. glutinosus*, *D. puberulus*, *D. sylvestris*, *D. microlepis* and *D. m. alba*, *Geranium grandiflorum*, *G. webbianum*, *G. wallichianum*, *Oxalis lobata*, *O. valdiviensis*, *Achillea Ageratum*, *A. Kellerei*, *A. Fraasi*, *A. tomentosa*, *Lithospermum graminifolium*, *Edraianthus divaricus*, *Cyclamens*, *Linaria alpina* and *L. a. rosea*, *Potentilla* Miss Willmott, *Helianthemums* in many varieties, *Anthyllis Vulneraria rubra*, *Arctotis aureola*, *Plumbago Larpenae*, *Ceratostigma willmottiana*, *Rosa pumila*, *Scabiosa graminifolia*, *Alyssum tortuosum*, *Cytisus schipkaensis*, *C. arleyanus*, *Centaurea speciosa*, *Alyssum rostratum*, *Scutellaria indica japonica*, *Lactuca perennis*, *Modiola geranioides*, *Tunica Saxifraga*, *Ranunculus creticus*, *Carlina acaulis*, *Iberis saxatilis*, *Primula capitata*, *P. lichiangensis*, *Sideritis hyssopifolia*, *Senecio Cineraria*, *Origanum hybridum*, *Silene swertiaefolia*, *Heliotropium anchusae-folium*, *Polygonum sphaerostachyum*, *P. capitatum*, *Verbascum Purpuri*, *Nepeta prostrata*, *Urtica acaulis*, *Pratia arenaria*, *P. angulata*, and several others.

One of the greatest charms of a rock garden lies in the succession of flowers always following each other and never entirely ceasing, however unfavourable the weather may be. The variety of aspect and position affords such protection and encouragement that plants cannot but respond. It is for this reason that even a small amount of elevation and broken surface possesses so many advantages over the flat bed.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SIX VARIETIES OF CHRYSANTHEMUMS (B. F. J.).—The following varieties flower outdoors from the early part of October to the middle of November, and all are splendid for lifting and potting when the buds are formed: *Caprice du Printemps*, rosy pink, tipped white; *Kathleen Thompson*, chestnut crimson, tipped gold; *Red Cap*, terra-cotta red; *White Cap*, pure white; *Surprise*, rosy cream; and *Dr. G. Barre*, reddish purple. Firms advertising *Chrysanthemums* in THE GARDEN would supply you with good cuttings or plants.

LIFTING GLADIOLUS CHILDSII (E. M. H.).—Your plants appear to be exceptionally late in flowering, the result, probably, of a proportionately late planting. So long as severe frosts are not experienced, however, and provided also that the bulbs (corms) are less than 4 inches deep, little harm will ensue at the moment, and they may be left a week or two longer with impunity. What is most likely to happen is that small, inferior-sized corms will result as the outcome of the late growth and flowering, which in turn will militate against a good display next year. You do not say when the bulbs were planted; but, assuming they were planted in March—their proper season—they should have been in flower by the end of August, when all would have been well. We can only advise you to leave them in the ground as long as possible and protect against severe frost.

THE GREENHOUSE.

AURICULAS AND PRIMULA MALACOIDES ATTACKED (North Cotswold).—The appearance of the leaves sent suggests the attack of thrips, but your description suggests white fly. We do not, however, see any of the scale-like larvae of that insect. Your best plan would be to fumigate with one of the recognised fumigants, and to dip the plants in a sulphur and soft soap dip made by taking a handful of soft soap and kneading thoroughly into it some flowers of sulphur, afterwards dissolving the mixture in 1½ gallons of hot water.

MARGUERITE MRS. F. SANDER (L.).—Plants of this *Marguerite* which have been bedded out this year are not likely to give satisfaction if kept over for another season. In order to obtain a stock of good bedding plants for next year, cuttings should have been taken towards the latter part of August or the first half of September, at which time they will readily root if put in a cold frame and shaded from bright sunshine. Plants so obtained do not take up much room during the winter months, which is often a great consideration, and if the points are pinched out when large enough, by the bedding period they form neat little specimens that will grow away freely when planted out. Plants of this *Chrysanthemum* that have been flowering outside during the summer are sometimes lifted and potted for winter flowering, but they are seldom worth the trouble taken. In any attempt to deal with the plants so as to give them a chance for another season's bedding, the better way will be to lift them, shorten the roots and tops, and put them in comparatively small pots, giving them a good place in the greenhouse. The roots are, as a rule, straggling and not well furnished with fibres, so that they would suffer too much from the check of removal to support the whole of their tops.

FRUIT GARDEN.

PEAR LEAVES FOR INSPECTION (Sunflower).—The Pear trees are attacked by the Pear-leaf-blister mite (*Eriophyes pyri*). Spray them in winter with the Oregon wash, made with caustic soda, lime, sulphur and salt, according to the formula we have several times given in these columns.

SEEDLING APPLES (G. Young).—There is always a special interest attached to those plants grown by one's self from seed, and therefore we suggest that you graft a few and let the others (as many as you choose) grow on their own roots. They will fruit right enough some time, but not nearly so soon as those grafted.

FIG TREE TO PRUNE (G. S.).—The way to prune a Fig tree is very simple. All you have to do is to cut out the thinnest and poorest of the shoots where they appear to be overcrowded. The foliage of the Fig is so large that if the branches are not well thinned out at pruning-time

in winter, the tree in summer becomes overcrowded and the branches of the present year's growth which produce the fruit of next year fail to ripen and bear good crops the year following in consequence.

KITCHEN GARDEN.

FORCING SEAKALE (P. J. S.).—Make your fermenting bed a foot larger all round than your frame. This will enable you later on to add linings of fermenting materials round your frame to keep up its warmth. Retarded roots are not to be had. Good roots of this year's growth are available, and they should now be introduced into moderate heat. But, of course, the produce will be small and weak compared to that grown later under the same conditions. Your best way will be to plant the roots close together in large pots or boxes, and plunge in the frames as soon as the bottom-heat has gone down to 70° Fahr. Keep up a good warmth in the day with sun-heat, and at night by covering the frame with mats.

MISCELLANEOUS.

THE SEMI-DOUBLE FLOWERED PINK PEACH (L. S.).—This is only of use as an ornamental tree. It flowers so early that its blossoms are generally destroyed by frost, so that it seldom bears fruit. We have partaken of the fruit with no serious consequences, but generally it is not thought of much account.

THE CAPER SPURGE AND THE TRUE CAPER (O. G.).—The fruits of *Euphorbia Lathyris*, the *Caper Spurge*, possess mild poisonous properties, and certainly cannot be used for *Caper sauce*. Some use was formerly made of a drug, *Euphorbium*, obtained from several species of *Euphorbia*, as an emetic and purgative, but, being violent in action, is very rarely used in medicine at the present day. The true *Caper* is *Capparis spinosa*, a shrub cultivated in Sicily and France.

MALFORMED HONESTY, AND OTHER QUESTIONS (J. S.).—The Onion was too far gone to enable us to say what the fungus was, and no fruit was visible on the leaves of the *Canterbury Bell*. The fungus on the *Goat's Rue* was *Cladosporium herbarum*, a very common fungus. You will notice the hyphae were somewhat coloured, not clear as in *Ramularia*. The divided septa of the *Honesty* are very interesting, and we must congratulate you upon your eye for things somewhat out of the ordinary, for they could not have been very conspicuous.

LAYING OUT A GARDEN (W. Willmott).—There is much that you might introduce into the garden to make it attractive, but we fear with the space at disposal there is not much room for plants for profit, and you give us no idea as to whether you possess any practical knowledge of horticulture. With a 7 feet or 8 feet high brick wall on the south side, cordon or other fruit trees might be profitably grown, with, in addition, a row of dessert Apples in the border 8 feet or so away. We are assuming the land is suitable for fruit-growing, as you suggest a row of fruit trees, though you say nothing about the nature of the soil or its depth. Planted 10 feet asunder, the border would accommodate fifteen trees, say, two each of *Plums Victoria*, *Monarch* and *Langley Bullace*; two each of *Apples Lane's Prince Albert*, *Allington Pippin* and *Wellington*, and three of *Cox's Orange Pippin*. The north-west border might be planted with a collection of herbaceous plants for cutting, with *Roses*, *Carnations*, *Pinks* and *Spanish Irises*. The row of *Poplars* planted at this side will be a drawback to the border if not kept in check. The kitchen garden space would be best planted with *Gooseberries* and *Black* and *Red Currants* at the margin, and otherwise cropped in season with *Carrots*, *Turnips*, *Beet*, *French Beans*, and *Peas* for succession.

CEANOTHUS AND LITHOSPERMUM (C. A. P. O.).—The former may be increased by layers or by cuttings of the young shoots inserted in slight heat from June to August. It is excellent as a wall plant, and shows to good advantage in a group on the lawn. The shrubbery is not the best place for it, unless it be one devoted to choice plants. The *Lithospermum* may be propagated by means of inch-long unflowered pieces detached with a heel from the parent stem and inserted in July or August, or by means of ordinary—that is, joint-made—cuttings of quite young wood. The old flowering pieces are valueless. In the former month a cold frame or hand-light would suffice, though they root quite well in a greenhouse temperature of 45° or 50° if covered by a bell-glass. Sandy or peaty soil is best. There are two forms of this plant—the type, which has dark-coloured flowers, and that known as *Heavenly Blue*, which, while more free in flowering, is also of a lighter blue colour and generally the better plant. If you could send us a sample of the water weed in a tin box, we should be better able to advise you concerning its destruction. Sulphate of copper would be injurious to other water plants, and fatal to fish, did such exist.

NAMES OF FRUIT.—R. H. B.—*Cornish Gilliflower*.—L. C. F.—*Catville Blanche*.

NAMES OF PLANTS.—A. L. N.—1, *Muehlenbeckia varians*; 2, *Eucalyptus globulus*; 3, *Pyraecantha coccinea*; 4, *Lycesteria formosa*; 5, *Escallonia rubra*; 6, *Tropaeolum tuberosum*; 7, *Ailanthus glandulosus* (Tree of Heaven).—C. A. P. O.—1, *Berberis acuminata* (China), 3 feet high at present, but likely to grow taller. It is a new plant, and the size to which it develops in this country is not known; 2, *Berberis Hookeri* (Himalaya), 3 feet to 4 feet.—J. M. N.—*Erica stricta*, a native of South-Western Europe. We are interested to know that a large bush of this species has been in the same place for over twenty years.—H. C. M., *Jersey*.—*Datura Stramonium*, or the *Thorn Apple*.

SOCIETIES.

NATIONAL CHRYSANTHEMUM SOCIETY.

For the first time in the history of this society the annual exhibition was held at the Royal Horticultural Society's Hall, Vincent Square, Westminster, S.W., on Thursday and Friday, November 11 and 12. The building was well filled with a beautiful array of Chrysanthemums, in which all types were charmingly represented. The Japanese and singles were especially good, and we doubt whether they have ever been exhibited in better form and condition. The displays of the trade specialists were remarkably good, and were most artistically disposed. To Mr. R. A. Witty, the secretary, much credit is due for the excellence of the arrangements. The show closed at six o'clock each day, owing to the new lighting arrangements prevailing in the Metropolis.

TRADE DISPLAYS.

The trade made an excellent framework to the show with their very handsome groups, each exhibitor being allowed a space of equal dimensions.

Messrs. Clay and Sons presented a gold medal for the best miscellaneous exhibit of Chrysanthemums, the contest was most keenly fought, and the judges awarded this premier medal to Mr. Philip Ladds, Swanley Junction, Kent. His group was superbly disposed, and included Japanese blooms of splendid quality, singles as fine as we have ever seen them, and beautiful decorative sorts. Arranged and edged with foliage plants the effect was very striking. A large gold medal was also awarded to this group.

Messrs. W. Wells and Co., Merstham, Surrey, also showed extremely well, winning a large gold medal for their bold, attractive group. Huge Japanese Chrysanthemums were shown, such as Queen Mary, Mrs. R. Luxford, William Rigby, Mrs. R. C. Pulling, Mrs. E. C. Tickle, Edith Cavell and Daily Mail. Single and decorative sorts were also exhibited in this fine group.

Mr. Norman Davis, Framfield, Sussex, won a gold medal for an artistically arranged group of Japanese, singles, incurved and other types of the flower. Handsome foliage plants were beautifully interspersed, and the effect was very fine indeed.

To H. J. Jones' Nurseries, Limited, Lewisham, S.E., a small gold medal was awarded for a group that seemed to lose some of its effect by the use of a background of white paper. Large Japanese, incurved, single, Pompon and decorative sorts were disposed in pleasing fashion. There were many dainty things in this exhibit, and everything was very fresh. This was a splendid representative display.

A silver-gilt medal was awarded to Messrs. W. J. Godfrey and Son, Exmouth, Devon, for a table group of singles of a very varied and interesting character.

A small but effective table group of singles was shown by Mr. A. Robertson, 18, Abbey Road, St. John's Wood, N.W. The flowers were set up in Bamboo stands and vases most effectively, and the display was awarded a silver medal.

The Misses Price and Fyfe, Birchgrove, East Grinstead, had a specially bright and attractive table group of single Chrysanthemums. Miss Doris Hilder, L. Lawrence, Miss Goodburn and Max were especially noteworthy. Silver medal.

Messrs. Hobbies, Limited, Dereham, had a representative group of single Chrysanthemums, Roses, Dahlias and fruit, for which a large silver medal was awarded. The Apples were especially handsome and of good quality.

CUT BLOOMS.—JAPANESE.

The class open to affiliated societies for twelve vases of cut blooms found only one competitor, and first prize was awarded to the Finchley Chrysanthemum Society for a capital representation of large Japanese incurved. Singles and Pommoms were shown very well. The premier cut bloom class was one for thirty-six blooms of Japanese, distinct, and there were five exhibitors. A handsome series of blooms gained first prize for Mr. T. Stevenson, gardener to Mr. E. G. Mocatta, Woburn Place, Addlestone. Mrs. J. Gibson, Bob Pulling, Master James, Lady Talbot, Rosamund, A. F. Tofield, Mrs. G. Drabble, Frances Rowe, Miss A. E. Roope, Mrs. G. Lloyd Wigg, W. Turner, Mrs. H. Kemp, Mrs. R. Luxford, Mrs. R. C. Pulling and many other fine varieties were exhibited. Second prize was awarded to Mr. Jewell, gardener to Mr. T. H. Mann, Rotherfield, for a heavy lot of less interesting blooms. Third prize was secured by Mr. M. Sargent, gardener to Mr. G. L. Wigg, Rockshaw, Merstham, for a fresh lot of high quality flowers.

The nine exhibitors in the class for twenty-four Japanese blooms, distinct, made a remarkably fine display, all of the exhibitors showing well. Here again Mr. T. Stevenson led with a very heavy lot of blooms of the highest quality. We have never seen better Mrs. R. C. Pulling, Mrs. H. J. Stratton, Master James, Undaunted, Queen Mary, Mrs. E. A. Tickle, Mrs. Thomas Stevenson, James Gibson, Miss A. E. Roope and Mrs. G. L. Wigg. Mr. Sargent was placed second, his flowers being less highly coloured than those in the leading exhibit. A very commendable series gained third prize for Mr. H. C. Gardner, gardener to Lord Foley, Ruxley Lodge, Claygate. Bob Pulling, Rosamund and Queen Mary were very handsome.

The ten entries in the class for twelve Japanese blooms made a good show, and here again Mr. Stevenson excelled with a very even board of fine quality blooms. Mrs. J. Gibson, Lady Talbot, Miss A. E. Roope, Queen Mary and Mrs. R. C. Pulling were superb. A splendid series secured second prize for Mr. G. H. Clack, gardener to Lady Esmé Gordon, Paxton Park, St. Neots. Third

prize was won by Mr. H. Lloyd, gardener to Captain C. Wiener, Ewell Castle, Ewell.

Twelve exhibitors staged in the class for six blooms of Japanese, distinct, the first prize in this case being awarded to Mr. T. Pateman, gardener to Mr. C. A. Cain, J.P., Node Gardens, Welwyn, Herts, for a very heavy lot of grand blooms. Second prize was awarded to Mr. J. Lamon, gardener to Mr. C. W. Mann, Ravenswood, Bexley, for a clean lot of flowers; and to Mr. G. H. Clack third prize was placed to his credit for handsome blooms.

The eight exhibits in the class for one vase of six blooms of white Japanese made a very welcome show of chaste blossoms. First prize was won by Mr. T. Pateman with lovely blooms of W. Turner; second prize was awarded to Mr. H. Blakeway, gardener to Mr. W. H. Allen, Bromham House Gardens, Bedford, with good examples of Queen Mary; and third prize was placed to the credit of Mr. A. Smith, Convent Gardens, Southampton Lane, S.W., with Mrs. Gilbert Drabble.

Six competitors in the class for one vase of six Japanese blooms, one variety of a yellow colour, made a distinctly good show. Superb examples of Mrs. R. C. Pulling gained first prize for Mr. H. Blakeway; second prize was secured by Mr. M. Sargent with the same variety; and with grand specimens of F. S. Vallis, Mr. T. Pateman was a good third.

CUT BLOOMS.—INCURVED.

Three exhibits in the class for twenty-four incurved blooms, distinct, were of fair order, by far the best coming from Mr. E. Dore, gardener to Mr. H. Bennett, Abbeyfield, Bickley, Kent, with a good series of well-finished blooms. Maritana, Clara Wells, Romance, Pantia Ralli, Percy Wiseman, Mont Brunn, Mrs. Barnard Hankey and Charles Hall were some of the better flowers.

SINGLES, POMPONS, &c.

A grand class was that for twelve vases of disbudded blooms, and this included both double and single flowers. Japanese were Yellow Moneymaker, T. Page, Pioneer (incurved), Crimson King, Freda Bedford and E. Cox. Singles were, Ceres, Merstham Jewel, Yellow Merstham Jewel, Max, Molly Godfrey and Sandown Radiance; a superb exhibit that well deserved the first prize it gained. This came from Messrs. Cragg, Harrison and Cragg, Heston, Hounslow, Middlesex. The same firm secured leading honours for six vases of Anemone blooms, showing Aphrodite, their new mauve pink variety. Second prize was won by Mr. P. J. Broom with distinct sorts, such as Mr. H. Eland, Moreen Jones, Mrs. Shimmins, J. Bunyan, Delaware and Mme. C. Lebecqz.

Pommoms were charming and there was a goodly array of them. First prize went to Mr. J. W. Hussey, Malforch Lodge, Exeter, having overlarge blooms, which lost considerably thereby. A pretty series secured second place for Mr. F. Fitzwater, gardener to Mr. C. Urban, Bushey Lodge, Teddington, Black Douglas, Prince of Orange, Mme. Elise Dordan and William Westlake being charming. Mr. A. Robertson won third prize.

The class for a vase of singles, arranged for decorative effect, is always an interesting exhibit. Mr. T. Stevenson led with a heavy, compact arrangement that pleased few. A charmingly arranged vase of good flowers and set up most artistically won second prize for Mr. D. B. Crane, Archway Road, Highgate. Many visitors preferred the latter. Mr. A. Robertson was third.

SOUTHAMPTON CHRYSANTHEMUM SHOW.

A VERY beautiful exhibition of flowers, fruits and vegetables was held recently in the Pier Pavilion. There was a Red Cross stall; many exhibits were also sold to supplement this effort, and a large sum was realised.

The non-competitive exhibits of Messrs. Toogood and Sons, Southampton, who staged a fine collection of vegetables; Messrs. B. Ladhams, Limited, of Shirley, who staged remarkably fresh herbaceous cut flowers; Mr. E. Wills, Southampton, who had a charming display of stove and greenhouse plants; and Messrs. W. H. Rogers and Son, Limited, who put up a big collection of Apples and Pears, added much to the attractiveness of the show.

COMPETITIVE CLASSES.

Plants.—For six plants of Chrysanthemums suitable for conservatory decoration, Mr. S. Joyner, gardener to J. C. E. D'Este, Esq., was first. Mr. Allan Cooper had the best six plants of singles, and Mr. S. Joyner the winning four bush plants; these were also awarded the society's first-class certificate. This exhibitor won the cup and medal for five plants, Japanese or incurved, bearing not fewer than four blooms on each. Again he won in the class for three plants.

Vase Classes.—The blooms displayed were very fresh, large and refined. M. Gale, Esq. (gardener, Mr. W. H. Cole), Twyford, was the winner in the class for eighteen blooms, in six varieties; he had Kara Dow, Mrs. Lloyd Wigg, F. S. Vallis, Queen Mary, Fred Green and Lady Talbot, the latter being selected as the premier bloom. Second honours went to Captain F. J. Dalgety, Romsey (gardener, Mr. W. Baxter). He had His Majesty (grand), Queen Mary, F. S. Vallis, Mrs. Kinsly, Mrs. Tricker and Lady Talbot. Third, Ellen Lady Swaythling, Southampton (gardener, Mr. T. Hall). The varieties Mrs. G. Drabble and Francis Jolliffe were fine indeed in this collection.

In the class for four vases of decorative Chrysanthemums, Mr. T. Hall was first with Kathleen Thompson, White Caprice du Printemps, Pink Caprice and Source d'Or. Second, Mr. W. H. Cole. Mr. Cole had the first place in the class for six vases of singles, staging Ceddie Mason, Altrincham Yellow and Miss M. Pope in fine condition.

Mr. G. Ellwood, gardener to W. H. Myers, Esq., Bishop's Waltham, was first for one vase of blooms, not disbudded, arranged with any foliage.

Mr. A. H. Hill won in the class for twelve blooms, Japanese. R. C. Pulling, His Majesty, T. Payne and Francis Jolliffe were the best blooms; a first-class certificate was awarded to the last-named variety. Second, C. W. Greenhill, Esq., Warsash (gardener, Mr. W. Hoare); third, Mr. A. H. Tofield. Mr. A. H. Hill was first in the class for twelve blooms, Japanese, not fewer than eight varieties.

Blooms on Boards.—Mr W. Baxter scored in the class for eighteen blooms, very fresh. There were two each of Mrs. Kinsly, Mrs. T. Lunt, F. S. Vallis and Master James respectively; one each of Bessie Godfrey, Lady Talbot, Queen Mary, Daily Mail, Dandy, Mrs. W. Tricker, Mrs. G. Drabble, His Majesty, Mrs. R. Luxford and Mrs. T. Stevenson. Second, Mr. W. H. Cole; the variety Marie Loomes was exceptionally fine in this stand. Third, Mr. T. Hall. Mr. A. H. Hill was first for twelve blooms, Japanese, distinct; Mr. Tofield second.

Incurved blooms are still well grown and exhibited in the Southampton district. Mr. W. Hoare scored in the class for twelve blooms, distinct; he had W. Pascoe, H. W. Thorp, Frank Trestien, Miss Thelma Hartmann, Nellie Southam, Romance, Godfrey's Eclipse, Mrs. J. P. Bryce, Mrs. Heygate, Mrs. P. N. Wiseman (grand), and Mrs. G. Denyer. Second, Mr. W. H. Cole; third, Mr. T. Hall.

The following cups, held by the winners for one year, were awarded as follows: The Victorian Memorial Cup, value £40, to M. Gale, Esq.; the Challenge Trophy for Amateurs to A. H. Hill, Esq.; the Mazawattee Challenge Cup to Mr. S. Joyner.

NON-COMPETITIVE EXHIBITS.

Gold Medals.—Messrs. W. H. Rogers and Son, Limited, for Apples and Pears; Mr. E. Wills, stove and greenhouse plants; Messrs. Toogood and Sons, vegetables.

Silver-gilt Medals.—Messrs. Jarman and Co., Chard, for Apples; Messrs. B. Ladhams, Limited, herbaceous cut flowers.

BOURNEMOUTH AUTUMN SHOW.

THIS exhibition was held recently in the spacious Winter Gardens Pavilion, which lends itself so well to such displays. The various competitive groups, tables and stands of flowers, as well as the very important non-competitive groups staged by trade growers, all combined to make a very imposing and extremely attractive show. Messrs. James Cypher and Sons, Cheltenham, and Messrs. Charlesworth, Hayward's Heath, had lovely tables of Orchids; Messrs. Stuart Low and Co., Tree Carnations; Messrs. W. Watts and Sons, Limited, Bournemouth, groups of Chrysanthemums and shrubs; Messrs. Jarman and Co., Chard, hardy fruits; and Messrs. R. Veitch and Son, Exeter, hardy fruits and Carnations.

The classes for Chrysanthemums, in vases and on boards, were well filled with blooms of great size and high quality. The eighteen blooms staged by Major Wyndham Pain, Bransgore House, Christchurch, were much the best in the show; probably their equal are not to be found in any part of the country. They easily won the silver challenge cup, finally.

COMPETITIVE EXHIBITS.

The Park Nurseries, Limited (Mr. F. W. Welch, manager), were awarded first prize in the principal class for groups of miscellaneous plants and cut flowers.

Mrs. Ormond, Astney Firs, Bournemouth (gardener, Mr. C. Pearce), won the silver challenge cup in the class; for a group of Japanese and single-flowered Chrysanthemums; second, Surgeon-General W. C. Roe (gardener, Mr. W. Messer), Bournemouth; third, Mrs. Telfer (gardener, Mr. G. Galpin), Bournemouth. These were all charming groups, well arranged.

Cut Blooms in Vases.—For nine vases, three blooms in each, Sir Randolph Baker, Bart., M.P., Rantson House, Blandford (gardener, Mr. A. E. Usher), was first; he staged Joan Stratton, Master James, Miss A. E. Roope, Mrs. Lloyd Wigg, W. Turner, Mrs. R. C. Pulling, Miss A. E. Tickle, F. S. Vallis and Mrs. J. Gibson. Second, E. G. Mocatta, Esq., Addlestone, Surrey (gardener, Mr. T. Stevenson), who staged fine blooms; third honours went to Major Chichester (gardener, Mr. W. Hall), for lovely examples.

Mr. Stevenson had the best twelve vases of singles. Mrs. Walter Hemus, Mensa, Yellow Bird, Mrs. T. Humphrey, Sandown Radiance, Jessica, Tom Wren, Molly Godfrey, Mrs. Loo Thomson, Glorious, Portia and Mrs. T. Page were the varieties shown. Mr. F. G. Bealing, Southampton, was second.

Blooms on Boards.—Mr. A. E. Usher was the winner in the class for twenty-four cut blooms, staging Mrs. J. Gibson (2), Mrs. Lloyd Wigg, Miss A. E. Roope (2), Undaunted, J. Stratton, Master James, Lady Talbot, Miss E. D. Tickle, W. Vert, Queen Mary, Mrs. R. C. Pulling, Francis Jolliffe, F. S. Vallis, Pockett's Crimson, W. Turner (2), His Majesty and W. Rigby.

Fruit and Vegetables.—These were extensively staged. Mr. W. Hall was first in the classes for two bunches of white and black Grapes, respectively, Mr. W. Webb, gardener to Dr. Ramsay, Bournemouth, being second in the black Grape class with Mrs. Pince. Mr. Hall's Muscat of Alexandria were very fine. Mr. Webb scored in another class for two bunches of black Grapes, Mr. G. Garner second.

NON-COMPETITIVE EXHIBITS.

Gold Medals.—Messrs. Toogood and Sons, Southampton, for vegetables; Messrs. J. Cypher and Sons for Orchids; Messrs. Stuart Low and Co. for Carnations; Messrs. G. Watts and Sons, Limited, for stove and greenhouse plants; Messrs. R. Veitch and Son, Exeter, for hardy fruits; Messrs. Charlesworth and Co. for Orchids.

Silver Medals.—Mr. F. B. Summerbee for floral designs; Messrs. Jarman and Co. for Apples; and Messrs. John Waterer and Sons for shrubs.

THE GARDEN.

No. 2297.—VOL. LXXIX.

NOVEMBER 27, 1915.

NOTES OF THE WEEK.

The National Chrysanthemum Society.—

The executive committee of the National Chrysanthemum Society have decided to hold a show at the Royal Horticultural Hall, Vincent Square, Westminster, S.W., on November 9 and 10, 1916, and the necessary arrangements with regard to same have now been made.

Professor Lefroy's New Appointment.—

Professor Lefroy, who has served during the past year as entomologist to the Royal Horticultural Society, has accepted an urgent invitation from the Secretary of State for India to proceed to the East in order to carry out investigations of great economic importance.

Erigeron Quakeress.—

At the November meeting of the East Anglian Horticultural Club, one of the members, Mr. T. Notley, brought with him a fine bunch of the lavender blue flowers of *Erigeron Quakeress*, which he now has blooming profusely for the second time. This is unquestionably one of the very best of the newer varieties, of compact habit, requiring little staking. It is splendid both as a border plant and for cutting, and should not be forgotten at the present planting season.

Protecting Early Flowering Chrysanthemums.—

Now that these valuable plants are over, a few plants of each variety should be lifted and placed in a frame, covering the roots with leaves. They need very little attention. Plants treated in this way will give plenty of cuttings later; or they may be taken out and divided as soon as the new growths are far enough advanced.

A Beautiful Berried Tree.—

There is no hardier tree or shrub for thriving in town gardens than *Cotoneaster frigida*; it is certainly the most striking of all the *Cotoneasters*. Its clusters of bright red berries wreathing the branches form quite a picture during the autumn and early winter, sometimes remaining on the trees until February. The tree should be kept to one stem, removing the lower branches when young. It will then make a pretty, round-headed tree 20 feet high, with a well-shaped trunk.

The Golden-Fruited Yew.—

In the extensive collection of Yews at Kew, several trees or large bushes of *Taxus baccata fructu luteo* are conspicuous at the present time. They form a pleasing divergence to the red-fruited varieties, while the rich golden yellow colour is even more attractive.

This variety is said to have originated in Ireland about a hundred years ago. There may be many trees of it in cultivation, but as male and female flowers are borne on different plants, the fruits are not formed unless specimens of the two are in proximity.

Seedling Trees.—Mr. J. Fraser, at a recent meeting of the scientific committee of the Royal Horticultural Society, stated that he had recently found seedlings of a variety of trees on the Leatherhead Downs, twenty-seven in all, and that in one

6 inches long, with numerous spiny teeth round the margins. The flowers are a dull yellow, followed by purple black fruits in autumn. At this season some of the older leaves turn a rich golden yellow, flushed with red.

Bulbs for Convalescent Camps.—

The President of the Royal Horticultural Society recently appealed to home growers of bulbs for consignments of their surplus stock for standing and convalescent camps in France, to interest in gardening those men who are able to do a little work. We are

glad to hear that there has been a good response, bulbs to the weight of over one ton having been received and despatched for distribution through the medium of the Red Cross Society. The contributors are as follow: The Edinburgh Botanic Gardens, the Rev. J. Jacob, Messrs. Walter T. Ware, Dickson and Robinson, A. M. Wilson, Sutton and Sons, Carter Page and Co., Dickson, Brown and Tait, Robert Veitch, T. G. Brown, J. R. Pearson, W. H. Divers, W. Poupart, and Barr and Sons.

A Plant for Mossy Walls.—

A pretty little plant for wet, mossy walls near fountains, &c., is *Laurentia tenella* from Cyprus and other parts of the Southern Mediterranean. Its small leaflets form pretty, bright green tufts among the moss. The flowers are small and pale mauve, but appear in great abundance for a long succession from spring and extending through the summer. They are exactly like minute *Lobelia* flowers in shape, to which genus *Laurentia* is closely related. The plant will soon establish itself when rightly placed, and needs no care whatever.—A. E. B.

Collecting Horse Chestnuts.—

Children living in country districts can assist in increasing the home production of food in many ways. At present, if their parents keep pigs or other live-stock, they can help to reduce the cost of feeding by collecting Acorns and Horse Chestnuts, rough grass, &c., for use as fodder. They can also help to economise the use of straw for litter by collecting dried Bracken, grass, leaves and reeds. Suggestions for the use of these materials are given in leaflets issued by the Board of Agriculture and Fisheries, and while we give these suggestions our whole-hearted support, we are interested in the use for Horse Chestnuts, which are left untouched by most animals, except herds of deer, even in very hard winters.

ERIGERON QUAKERESS, A BEAUTIFUL BORDER PLANT THAT CONTINUES TO FLOWER UNTIL NOVEMBER.

gravel-pit he had found three species of *Lemna* (*L. polyrrhiza*, *L. minor* and *L. trisulca*), and the rare *Wolffia arrhiza*, the smallest of flowering plants.

A New Evergreen Barberry.—Among the numerous species of *Berberis* introduced from China by Mr. E. H. Wilson, *B. acuminata* is one of the most distinct. Specimens were collected in 1882 by the French missionary Abbé. Delavay, but it was not until 1900 that seeds were sent home by Mr. Wilson. It promises to form a fairly large bush, and has dark green leaves nearly

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Chrysanthemum arcticum.—I was glad to see the capital illustration and note on *Chrysanthemum arcticum* in *THE GARDEN* of November 6. I obtained this plant many years ago from the late Mr. Bruce Findlay, when paying a visit to the Manchester Botanic Gardens, then under his charge. I have had it ever since. With me it is not pure white, but faintly tinged with rose. Its two faults are the form of the blooms and its tendency to creep at the roots. This is an advantage when propagation is desired, but is sometimes a drawback to other plants in its vicinity.

—S. ARNOTT.

Sea Pinks as Edging to Rose Beds.

As edgings to narrow paved paths, Thrift is delightful. The two in combination give to a garden that old-fashioned touch which so many amateurs now desire. The round evergreen cushions prevent the soil from encroaching on to the paved walks, and keep the edging neat and prim without being exactly formal. The form illustrated is the ordinary deep rose variety. It is the most economical of plants, and yet one of the most floriferous. When the Roses first bloomed, every flower was cut from the Sea Pinks, as the colour was fading. We estimated that we cut 15,000 flowers from the plants—an average of fifty to the plant, and yet a few weeks later they were again as seen in the photograph. The Roses have gone, but the Sea Pinks are still in bloom, and look as if they might continue so until spring comes round again.—A. L. D., *Marple*.

Lapagerias Flowering Outside on North Walls.—You ask for information from your readers as to the outdoor cultivation of *Lapagerias*. I have several plants, some of them 10 feet high, growing well on north walls. They have been in flower already for several weeks, and will continue so until after Christmas. The white variety is included as well as the red, but seems less vigorous. In planting, a little peat was mixed with the natural soil (which is green-sand). I find that they do not do well on a south exposure, and they seem to require the shade of a north wall. Most of them have been out in their present position for six or seven years.—L. H., *Nuneham Park, Oxford*.

Passiflora edulis.—The edible Passion fruit, *Passiflora edulis*, which you illustrated and commended in your issue for November 13, page 551, is, I think, too little appreciated. It is a most pleasant fruit. I am not aware of any difficulty in the cultivation of it, and I know that the genus generally well repays attention under glass. I have endeavoured to obtain plants from firms of repute, but to my surprise there appears to be no demand for them, therefore I am obtaining seeds from Sydney, New South Wales, where the plant grows to perfection and is largely grown owing to public demand. In a part of the State I have seen

bird sown plants growing luxuriantly on moist river banks; but the moisture of a well manured and drained loam is sufficient, and when grown in such a medium fruit is certain; that is, in a climate where most of our cold and temperate house subjects grow outdoors. Given a warm wall in a greenhouse it ought to thrive. The fruit is not very ornamental, for when ripe it is only dull purple to dark brown, but the foliage when growing strongly is ornamental.—PRIVATE GARDENER.

Remedy for Club Root in Cabbage.—I recall some five years ago making an addition to the garden of a very rough piece of ground which I knew had never been broken up before. Now,

SEA PINKS BORDERING A NARROW PATHWAY.

this piece was bastard-trenched and laid rough till February, when I planted some six score of Cabbage Winningstadt of my own sowing. To my intense surprise the crop turned out a very poor one, and on examination I found club root to be the cause. The year after the ground was again dug over, and no manure added. I then made a mixture of water and clay to the consistency of cream—four gallons of water and twenty to thirty pounds of yellow clay, with half a pound of flowers of sulphur. I again planted the same variety of my own sowing. Each plant I dipped up to the leaves in this mixture and planted at once, taking care the mixture did not drop off. I awaited the result, and out of six score plants only three were bad. This is a remedy which answered successfully with me, but I cannot

say that it will suit all soils. I might also say that at the Chapel-en-le-Frith Horticultural Show that autumn I took the first prize from this plot in a strong class (open) for a pair of white Cabbages to be shown with roots.—PRIVATE H. W. BENNETT, 2369, A Company, 6th Sherwood Foresters, British Expeditionary Force, France.

Late-Flowering Climbers.—Is it not rather wonderful at this time of year to have a Passion Flower in full bloom? I have one now on the east side of this house, which gets very little sun owing to a projecting wing, on which I counted to-day (November 16) twenty-eight fully expanded blossoms, besides hundreds of others half open and in bud. Two nights ago we had over 20° of frost, while this morning the ground was white with snow—and mid-Oxfordshire can hardly boast a warm climate. I may mention besides that on the west side, facing the Passion Flower, I have a white *Solanum*, planted only a year and a half ago, which is 30 feet or more high, far beyond the gutter and straggling over the roof, also still smothered in bloom, in spite of the frost above mentioned. The courtyard both are growing in is paved; hence I believe their growth and hardiness.—A. LA T., *The Old Hall, Oxon*. [Although the specific names of the climbers are not given, there is little doubt that *Passiflora carulea* and *Solanum jasminoides* are intended, both of which we have recently seen flowering on sheltered walls and archways in Surrey. The fact that these plants are natives of Southern Brazil makes it all the more remarkable that they should continue to flower after the hard frosts we have lately experienced.—Ed.]

Plum Coe's Golden Drop and Pear

Pitmaston Duchess.—There is no questioning the fact that the Squire of Braziers is a thorough and capable judge of anything that is good in the fruit or floral line, but I think future pages of *THE GARDEN* will show that his condemnation of Plum Coe's Golden Drop on page 552, issue November 13, is a little severe and quite unmerited. It is not at all a bad plan for growers of this Plum to "forget" that it is included in their collection, and "quite accidentally" come across it late in October or the early days of November. Then I have heard the fruits likened to "bags of nectar." What if the skins are slightly tough? It is the "nectar" we are after and not the

"bags"; and are the latter any more difficult to dispose of than the skins of Grapes? I am fully in agreement that Pitmaston Duchess is not a first-rate Pear, and the faults mentioned by your esteemed correspondent are only too apparent; nevertheless, so long as Pear Pitmaston Duchess proves itself the reliable cropper it undoubtedly is, so long will it be grown. Size is no recommendation to the epicure; yet, let anyone pit a dish of that gem among Pears, Thompson's, against a dish of Pitmaston Duchess at a fruit exhibition, and you will find the latter the choice of the judges. Pear Doyenné du Comice can frequently give points to Pitmaston Duchess in size; but never yet have I heard an adverse criticism on this account.—HEATHER JOCK, *Hants*.

Black Spot on Roses.—In reply to "T. A. W." and others, there is no cure for black spot. Preventive remedies will, however, keep it in check, and these are: Pick off and gather all fallen leaves until a hard frost has made the plants dormant, then spray the plants and the ground with freshly made Bordeaux mixture. As soon as all the leaves are off the plants, gather them up and spray again, and spray twice a month until February, then use the soda form of Bordeaux with treacle, as the writer suggested in the Rose Annual for 1915, and soap sprays during the summer. The plants must be kept clean and free from all insect pests during the next summer. I do not think that "T. A. W.'s" Roses have black spot, but, instead, scale. All the Pernetiana Roses are very susceptible to scale; they catch it from the Briars and have a bad attack of it. The honey-dew from aphides and excretions from other pests will behave in much the same way. The treatment will be the same as above. If not a member of the National Rose Society, see some friend who is, and borrow the Annuals for 1913, 1914 and 1915 and carefully read them; but if you would have Roses you must clean up and keep clean at all times. All dead leaves and prunings must be promptly gathered up and burnt at once.—T. N. C.

A Simple Mouse-Trap for Use in the Garden.—I see in recent issues of THE GARDEN complaints of the damage done by mice. I was much bothered by these some time ago. I tried poison, but fresh mice came continually, so I found a trap the best remedy. I used old tins half filled with water, and a tin tilt with grease put in the middle. No. 1 shows the tin buried in the soil. No. 2, the water in the tin. No. 3.—At the point shown by the arrow a hole is made in the side of the tin to prevent the latter becoming full of water. Nos. 4, 4 depict a lump of grease fastened to the tilt on the cross wire. No. 5, the cross wire. No. 6, the tilt fastened to the latter, with small wire on the top of the tin. I have these traps round my kitchen garden, and the mice are taken out when dead. A hole must be punched in the tin, or it will become too full of water.—A. W. A., Smallfield Place, Horley, Surrey. [This kind of

Magenta Flowers.—I wonder whether any readers of THE GARDEN can supply me with names of good perennials of a real magenta colour. By "real magenta" I mean, not the ugly washy colours, but the deep rich colour found in dark Petunias and Geranium sanguineum. I am rearranging a hitherto unsatisfactory portion of a long herbaceous border, and hope to find that a mixture of red-purples and Petunia will give the depth and warmth of colour desired in that particular spot. I know many people are like Mr. Bowles and feel ill at the sight of the colour. I have always found it much admired when properly placed, but a certain amount depends upon the texture of the flowers. My present stock in trade consists of the Geranium, a few Petunia cuttings and some Dahlias, and as my border is very wide, I shall be grateful to anyone who can supply me with advice and names. I find I cannot

CÆSALPINIA JAPONICA & C. PULCHERRIMA.

By Miss Ellen Willmott, V.M.H.

FROM some notes upon Cæsalpinias in THE GARDEN, issue November 6, page 546, your readers might gather that Cæsalpinia japonica would only grow in favoured localities. I believe it is much hardier than it is usually given credit for. I have two plants in my garden which have stood the past twenty winters absolutely unscathed without any sort of protection. Originally planted against north and south walls respectively, they have long since grown into small trees and have made heads above the walls, and flower and fruit freely.

THE BARBADOS PRIDE (CÆSALPINIA PULCHERRIMA), WITH ACACIA-LIKE FOLIAGE.

obtain some of my old friends, such as English Iris Pharon and Lupine Ruby. The railway company took a fancy to my plants when I moved here.—MAGENTA.

Nerines.—The question whether Nerines are coming into favour, which is asked in THE GARDEN, must in my opinion be answered in the affirmative. The last twenty years have seen a vast improvement in the varieties brought forward, though some of the older kinds still hold their own. Complaints are by no means infrequent that Nerines cannot be depended upon to flower well. This is often the fault of the cultivator, who is far too tender-hearted to give them that thorough roasting after the leaves die off which is so necessary for the production of flowers. I have heard complaints that some varieties are not to be obtained from the ordinary trade sources. This need not occasion any surprise, as when Nerines are raised from seeds a good deal of variation will be found, even in the occupants of the same pod.—H. P.

If the Cæsalpinia can thus accommodate itself to my bleak, wind-swept garden at Warley, it could be grown with success almost anywhere, and it certainly merits a place in every garden. Its Fern-like foliage and distinct growth, together with its beautiful racemes of pale clear lemon-coloured blossoms with long red stamens, form a striking contrast to most of the shrubs and small trees usually seen in English gardens.

I have a tree of C. japonica some 25 feet high in my garden at Tresserve in Savoy, where the frost is of much longer duration and the winters far more rigorous than in England; but the Continental sun affords the wood better opportunities of ripening, and other conditions also differ.

Like so many of the Chinese and Japanese trees and shrubs, the habit of growth is picturesque and distinctive, and if pruned or lopped, much of its character is lost. Therefore, in planting, care should be taken to keep it well away from any pathway, so that ample space may be allowed

trap is also useful for catching moles in their runs, by sinking the trap below the run and not baiting it.—ED.]

for future development, as the stout, hooked thorns which arm its stems and leaves need to be given a wide berth.

This genus was named in honour of Andræus Cæsalpinus, an Italian botanist, and physician to Pope Clement VIII. It comprises some fifty species, mostly tropical or semi-tropical trees or shrubs. *C. pulcherrima*, the Barbados Pride, is the brightest and gayest of the genus. It succeeds well in a cool greenhouse with me, and if planted out in a sunny position, its beautiful red and yellow flowers will make a strikingly attractive feature in the border during the summer.

APPLE GASCOYNE'S SCARLET.

The accompanying illustration depicts this Apple growing as a bush in the garden at Aldenham House, and shows what, under good culture, a

WORK AMONG THE CHRYSANTHEMUMS.

THE harvest of blossom, after nearly a full year's labour, is now being reaped. Many thousands of blooms are being sent to the hospitals, where they will be much appreciated by our brave defenders. Not a single flower should be wasted; take the greatest care of all, for whatever special purpose they may be grown.

Excessive Damp.—This is one of the worst enemies of the flowers, and the larger the blooms and the more substantial the petals, the more likely they are to become victims to excessive damp. There is one specially good point the Chrysanthemum possesses, namely, its good flowering qualities and the freshness of the flowers over a long period without being aided by fire-heat, and as

rays will not readily reach them, the whites and yellows being arranged in the sunniest positions.

Immediately above very choice blooms that are approaching full development fasten sheets of white blotting paper; the paper will arrest and absorb the moisture as it falls and condenses during the night, and thus prevents it affecting the petals to a serious extent.

Feeding.—The excessive feeding of the plants at this stage is responsible for much damping of flowers. Rely chiefly now on clear water, and apply it early in the day. Where possible, place the plants well apart so that air can freely pass between them.

AVON.

NEW CHRYSANTHEMUM APHRODITE.

It is such an unusual occurrence for an Anemone-flowered Chrysanthemum to receive a special award that the card of commendation recently granted by the National Chrysanthemum Society to the variety Aphrodite is an incident worthy of more than a passing reference. The Anemone-flowered Chrysanthemum is an old type of flower that has, unlike the Japanese Chrysanthemum, been almost overlooked. The Anemone or Quilled Aster flowered Chrysanthemum as it used to be called has an outer symmetrical ring or rings of strap-like ray florets, and tubular disc florets densely arranged in a cushion-like boss in the centre of the flower. The blooms at first sight resemble Scabious or Pincushion Flowers. The variety Aphrodite has self mauve pink flowers. In addition to the honour already mentioned, the exhibitors, Messrs. Cragg, Harrison and Cragg of Heston, Hounslow, Middlesex, also secured with this variety the premier award for six vases of Anemone-flowered blooms.

HARDY CLERODENDRONS

CLERODENDRON FARGESII is one of the small trees or large shrubs introduced from Western China some nine or ten years ago, and is a decided acquisition to our gardens. If allowed to develop

naturally it forms a large bush some 10 feet or more in height and about the same in diameter, covered in late August and throughout September with clusters of white, star-like flowers. The latter are produced terminally, and are individually a little over an inch across, five-petalled, and have a scent strongly reminiscent of Paper-white Narcissus. The calyces are deep pink and the flowers are followed by china blue berries about the size of small Peas, and are very attractive, hanging on the plant until December.

The older and better known *C. trichotomum* is also in bloom at the same time, but *C. Fargesii* is the better species of the two for garden purposes. The latter is, on the whole, hardier, also more floriferous. Both are easily raised from seed, which is freely produced, and cuttings of half-ripened wood will also strike, though not very readily.

J. C.

APPLE GASCOYNE'S SCARLET, CARRYING A HEAVY CROP IN ALDENHAM HOUSE GARDENS, HERTS.

grand Apple it is, even for those with limited space. Considering the huge crop this tree bore, the fruit was of full size and the colour magnificent—a rich crimson, suffused with that soft plum-like bloom this Apple is noted for. I find in its earlier stages of growth some attention is needed at the roots to induce fruitfulness, the growth being vigorous. When well established the trees crop annually, as a rule. Grown as an espalier it succeeds admirably, or as a cordon in the open. Its season is really November and December for cooking. For dessert, too, there are many worse Apples, while it is held in great repute as a market variety and at the present time is sold in large quantities in Covent Garden. The variety was raised by Mr. Gascoyne of Bapchild, Sittingbourne, and was introduced by Messrs. G. Bunyard and Son in 1871.

E. M. S.

economy in fuel is a consideration, close attention must be paid to ventilation.

Take advantage of every hour of bright sunshine to admit air, especially while the atmosphere outside is dry. Reduce the ventilation in the afternoon to exclude damp, and almost close the front ventilators at night. Open the top ventilators early in the morning to get the petals dry before the sun shines on them. The sun shining on the blooms while there is condensed moisture on them soon causes burning and decay.

Bronze, chestnut, crimson and reddish crimson colours suffer most from scalding, the reddish crimson most of all. Lilac, mauve and pink colours suffer next; white, cream and yellow colours suffer least. Blooms which burn and scald soonest should be shaded more than the others. Plants bearing flowers of these colours, and also purples, should be placed where the sun's

BORDER CARNATIONS.

By J. L. GIBSON.

I WOULD like to discuss in this article the formation of a small collection of border Carnations for amateurs. One gleans from many sources ideas and suggestions meant to guide the uninitiated; books on the subject; articles in the gardening Press; answers to correspondents; hints from growers; they all give lists of desirable varieties, and doubtless many beginners have been wisely guided by these helps. But I have seen so many obviously indefensible lists submitted for this purpose that I propose to make a bold bid for criticism by declaring the following selection as a trustworthy guide to those who, desirous of starting a small but good collection of Carnations, have not the experience to profit themselves to the best advantage by wading through the catalogues of trade growers.

There are, however, two points to be borne in mind when this selection is criticised by keen-eyed readers who may like to differ. In the first place, many amateurs who regularly grow Carnations in the open borders only know the flower as there produced, fashioned and

shaped to a great extent by the whimsical and capricious changes of the British climate. Some at least of these amateurs possess glass-houses, and I want to induce all who can to cultivate a few plants inside, and the varieties below which are marked with an asterisk will do better there than they do in the border. Secondly, though economy must be a prime consideration in these war-fraught days, I hold that cheapness and economy are by no means synonymous terms; so, while omitting the very newest varieties as being both expensive and only partially tested, I have selected two dozen sorts irrespective of price, because, I take it, most

THE NEW CARNATION DAISY WALKER.

ANEMONE-FLOWERED CHRYSANTHEMUM APHRODITE.

of us would feel it unworthy if we saved sixpence on a plant and secured the second best instead of the best.

I can at least guarantee that the following will give abundant satisfaction to all who know how to grow the Carnation: Beau Nash, Bookham Clove, Bookham White, Border Yellow, *Daffodil, Daisy Walker, Edenside, Elizabeth Shifner, *Ellen Douglas, Gordon Douglas, Ibis, Innocence, *Lieutenant Shackleton, Miss Rose Josephs, *Miss Willmott, Mrs. Andrew Brotherston, Mrs. George Marshall, Mrs. Griffith Jones, *Pasquin, Rosy Morn, *Solfaterra, The King, Zulu and Ziska.

The illustration depicts the fine new white-ground fancy Daisy Walker, and admirably shows the perfect shape of the flower and delicate pencilling of rosy scarlet on the pure white ground.

There are many other named Carnations, of course, that larger growers would not think of doing without, but I am prepared for anyone who cares to cross swords with me in a friendly bout of argument as to the foregoing. If a wider range can be indulged in, there are Amazon, a beautifully formed flower of true Venetian red colour—quite unique; Annie Laurie, flesh coloured, very fine; Brilliant, a dazzling scarlet and a good doer; Caprice, pink with rose spots, perfect shape, a great favourite of mine; Dora Blick, a most beautiful flower, not too strong in the stem; Forester, a fine, rich-coloured fancy; Fujiyama, one of the best dark reds; Greyhound, silvery lavender; Helen Countess of Radnor, deep crimson, very good in the open; Linkman, Lord Steyne and Mandarin, good fancies; Montrose, white-ground fancy, excellent grower; Mrs. H. L. Hunt, a very delicate, sweet-looking flower, but its constitution might be stronger; Mrs. Robert Morton, an apricot self that does well anywhere; Sweetheart and Virginia, both beautiful fancies.

Having selected one's stock, a most important item is to get the plants from a good source. Cheap

offers should be shunned, as many traps lie open to the unwary buyer. Weak plants, disease-infected stock and other troubles surely await the innocent who so knowingly saves a few shillings on his order.

ROSES FOR PILLARS.

SINCE the introduction of Crimson Rambler nearly twenty years ago, the cultivation of Roses has undergone a great change, a change that has

flowers on wichuraiana or multiflora hybrids are by no means beyond the bounds of possibility.

The greatest change that these rambling Roses have brought about in our gardens during recent years is their cultivation as pillar plants. During July I was greatly interested in many beautiful examples in the counties of Essex and Suffolk, plants tied loosely to posts some 8 feet or even more in height, and each bedecked with its glorious and fragrant blooms from base to summit. The effect of such plants in a Rose garden is most beautiful and pleasing, and no great amount of skill is required to bring into

being Rose pillars of this description. The best posts that I have seen used for the purpose were some young Scotch Pines, about 6 inches in diameter at the base. When these were felled the branches were left about a foot long right up the trunk, so that the wands of the Roses could be tied to them, each pillar thus being about 2 feet in diameter before the leaves of the Roses were developed. When in full growth and flower the effect was most beautiful, the diameter of some strong-growing varieties, such as Mme. d'Arblay, being nearly 4 feet. Apart from the unique effect, the side branches of the posts prevented the growths of the Roses swaying about in the wind, as they are apt to do when a smooth, round post only is used.

In some gardens there are old fruit or other trees that are of no value, and which, if left alone, are little more than blots on the landscape. Yet the owner, for some reason or other, may not wish to have them removed, and it is here that our pillar Roses may be utilised. Indeed, the effect of such trees when clothed with Roses is better even than on the dead posts already mentioned. To clothe such trees with Roses is not

difficult, providing we select free-growing varieties and remember to plant them some distance from the trunks of the trees. It is also necessary to well prepare the soil, entirely removing some of the old and replacing it with good stiff loam. The accompanying illustration of Blush Rambler serves to indicate what a very beautiful effect may be obtained without much expense. The trees, too, have the advantage over dead posts, inasmuch as they last for a very long time and do not collapse just when the Roses have become well established.

Another secret of success in growing these pillar Roses is undoubtedly, with the majority of

varieties, light pruning. By this I do not mean that this important operation should be entirely neglected, but instead of cutting the shoots hard back, as is usually done, a thinning out of old wood would be far more beneficial. This, too, should, in most cases, be done as soon after the plants have flowered as possible.

Pruning Pillar Roses.—With Crimson Rambler it is best to cut the old wood right down to the ground, and rely each year upon the new, wand-like growths that are pushed up from the base. With the wichuraiana section, however, this plan would not always answer, because it frequently happens that the strongest new shoots are produced from the old wood some distance from the soil. But we cannot do wrong with any rambling Rose if we sacrifice old wood to make room for vigorous young shoots, no matter what part of the plant these spring from. If the old wood is cut out as early as possible after the flowers have faded, the young growths have a good opportunity of becoming well ripened before the winter, and are thereby better enabled to withstand frost.

Climbing Roses with large Blooms.—Although the rambling Roses of the multiflora and wichuraiana sections are very beautiful and pleasing to most lovers of Roses, they do not find favour with all, on account of their small blooms; hence recourse must be had to varieties with large flowers. Happily, there are a number of these available, one of the best being Ards Rover, with its beautiful crimson and fragrant blooms. Another old variety that I have noticed doing well in pillar form is Mme. Isaac Pereire. This is a Boursault Rose, with very large and full blooms of rose carmine colour, and one that I have a great liking for. In common with most of its section, it is deliciously fragrant, and for this feature alone is well worth a place in the garden. Tea Rambler, a beautiful climbing Tea Rose, is also excellent in pillar form. Its flowers, though not so large as those of the foregoing, are of good size and quite suitable for cutting, while the charming coppery pink colour always meets with a good reception. Billiard et Barré (a climbing Tea with golden yellow flowers), Climbing Mrs. W. J. Grant, Climbing Snow Queen Climbing Captain Christy, Climbing La France, Grüss an Teplitz (with crimson and fragrant flowers), Gustave Regis (pale yellow), Lady Waterlow (pale salmon pink), and the Thornless Rose, Zephyrine Drouhin, are others with large flowers that we may utilise for our pillars.

Other Roses for Pillars are Blush Rambler, Crimson Rambler, Carmine Pillar, Dorothy Perkins and Hiawatha, all of them too well known to need more than passing mention. A variety that pleased the writer very much last season was Tausendschön. This has bunches of glorious frilled flowers of the most pleasing shade of shell pink. Goldfinch is a very fragrant Rose with semi-double blooms. The buds are golden yellow in character, but the open blooms fade to deep cream. It is a splendid pillar Rose. Rubin is another good pillar Rose that is not much known. Its colour is described as deep crimson, but it is of quite a different shade to Crimson Rambler. It flowers very freely, but, owing to its peculiar colour, ought not to be planted near other crimson or scarlet varieties. Edmond Proust (flesh pink with carmine centre), Elise Robichon (pale rosy yellow), Mrs. F. W. Flight (bright pink) and Paul Transon (salmon pink) are all good pillar Roses that are not cultivated so extensively as their merits demand.

H.

BLUSH RAMBLER AND LAVENDER AT WARLEY PLACE, ESSEX.

added charm and beauty to gardens of all kinds; and although we may lament the passing from cottage gardens of the Old Damask and Monthly Roses, we cannot but admit that their places have been filled by others which are even more beautiful and pleasing. Hybridists have been so busy with the Japanese or wichuraiana Rose that we now have a wonderful host to select from, a host that is almost as varied in form and colour as the older and perhaps better known bush Roses. It is true that they do not yet possess the large, full blooms of such varieties as Ards Rover or Climbing Caroline Testout; but when we remember what has been done during the last decade, such

THE HEATH GARDEN IN AUTUMN.

THE Cornish Heath, with its thick carpet of purplish rose flowers, is one of the glories of an autumn garden. It is appropriately named. *Erica vagans*, meaning the Wandering Heath, for it is seen in its happiest mood when encroaching over a garden pathway or spreading among Pines, Arbutuses, Tree Heaths, and other tall-growing trees and shrubs. In a like manner

Heaths are backed by Rhododendrons, and overshadowed by Oaks and coniferous trees. In these congenial surroundings the Heaths never fail to give satisfaction. True, the soil is naturally suited to them, for Pine woods and Heather form the leading vegetation of the surrounding country, and it needs but a glance at the bright patches of Ling or Heather of this Surrey moorland to convince one that this is an ideal site for a Heath garden. To return to the Cornish Heath, there are many varieties, but *E. vagans grandiflora* is certainly the best of them. Its rosy pink flowers are thickly set and the racemes are borne

tomentosa and *tomentosa alba*, with spiky inflorescences rising about 18 inches from the ground, with rose and white flowers respectively, are among the very latest of the Heaths to flower. The garden varieties *Hammondii*, *Searlei* and *Alportii* are three of the best in cultivation, and although now past their best, are still flowering fairly well. But the glory of the Heath garden does not depend entirely on the Heather bloom, although flowers are there in every month of the year. *E. lusitanica*, with its tall plumes of dense green foliage, is very beautiful; while the low-growing *E. mediterranea hybrida* and *E. carnea* are both

THE CORNISH HEATH ON THE MARGIN OF THE WOODLAND AT KEW.

it spreads on the moorlands of Cornwall, Ireland and in the South of France. In Cornwall, however, it is abundant, and the white form, *alba*, also occurs there. It is a splendid subject for growing in large, informal masses around the edges of the woodland, and here let it be said that Heaths should always be grown in natural groups and, for preference, in close proximity to trees. Heaths grown in beds of formal design—and, sad to relate, they are still grown that way in many gardens of repute—are shorn of all their natural beauty. The Heath garden at Wisley is a good example of what a Heath garden should be. At all times of the year it is interesting and beautiful. The

freely. The flowers of *St. Dabeoc's* Heath are now passing over, but the late and gracefully drooping blooms in many colours, crimson, purple and white, are especially welcome when in season.

Erica ciliaris maweana, a deep claret red variety of the Dorset Heath, is one of the gems among October-flowering Heathers. It makes low-spreading tufts and is perfectly hardy. It is a native of Portugal. The type, *E. ciliaris*, occurs wild in Dorset and Cornwall, and it is one of the most delightful of dwarf Heaths in late summer and early autumn.

The common Heather of our moors, *Calluna vulgaris*, or common Ling, and its varieties

full of bud, and give a wonderful promise of bloom from January onwards.

Then there are a few peat-loving plants suitable for growing among the Heaths, such as *Kalmia angustifolia* and *Cyrilla racemiflora*, that flower in autumn. The former has heads of deep rosy flowers; the latter shrub grows to a height of 6 feet and bears in whorls dainty racemes of creamy white flowers. *Enkianthus campanulatus*, with its crimson and bronze foliage and its orange-tinted fruits, curiously twisted upside down, might also be included. Leaves may fall and flowers fade, but the Heath garden is the embodiment of brightness at all times of the year.

C. Q.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Propagating Young Vines.—These are readily propagated by cuttings or "eyes" planted early in the New Year. Now is the time to select suitable shoots for this purpose. Shoots of moderate strength and thoroughly matured must be retained when pruning the old Vines. Tie them in bundles, carefully label them, and heel them in at the foot of a north wall.

Pot Fruit Trees.—Where a number of fruit trees are grown in pots or tubs, it is wise to pot up a few "maidens" every year to replace or supplement older trees. Lose no time in potting them up when they arrive from the nursery. Pots 8 inches or 9 inches in diameter are ample for the first year or two. Cut well back the strong roots to encourage fibre. See that the pots are well drained, or the soil will become water-logged and sour before the roots have taken a firm hold. Plunge them in ashes or Bracken in a position which is somewhat sheltered from heavy rains. Pruning must not be done till the spring. They may then be cut back to four or five buds.

Plants Under Glass.

Bulbs.—It will be necessary to examine bulbs which are plunged in ashes, and if growth is active they must be taken from the ashes and placed in a cold frame. A few pots of early Tulips, such as *Proserpine*, and some of the early *Narcissi* may now be placed in the forcing-house if they are well rooted. *Narcissi* must not be forced too hard till the flower-buds are showing. Bulbs in frames must be protected from rats and mice, which are very destructive.

Poinsettias.—Keep the atmosphere dry, but afford water to the roots as often as they require it. When the bracts are fully developed, feeding must be discontinued. At this stage a temperature of 50° or 55° will be ample. A little air should be admitted through the top ventilators whenever the weather will allow.

Palms.—To keep Palms in a healthy condition, it is necessary to give them a thorough cleaning annually. In bad weather, labour can sometimes be spared from outside for this work. Scale is one of the worst enemies of the Palm, and if not removed the leaves soon develop a sickly appearance. This work must be done carefully, for the fronds are easily damaged. Strong soft soapy water and a sponge will readily remove this pest. When all the plants have been thoroughly cleaned, cleanse the house before rearranging the plants.

The Flower Garden.

Shrubberies.—The planting of deciduous shrubs should be finished as soon as possible. When this work is completed, the shrubberies should be cleared of fallen leaves and rubbish, and the ground dug. Leaves may with advantage be dug into the ground. Many surplus herbaceous plants may be made use of in front of the shrubbery.

Salvia Pitcheri.—This beautiful *Salvia* deserves to be more generally grown outdoors. It is, however, necessary to give it a sheltered position, such as at the foot of a wall facing south. Here we have it interspersed with outdoor *Chrysanthemums*, with admirable effect. In a sheltered situation this plant will winter safely outdoors. It is easily propagated by cuttings inserted in the spring, or by division of the roots.

Tropæolum speciosum.—If it is desired to propagate this beautiful *Tropæolum*, the tubers should be dug up, divided, and set in boxes or pans and placed in a cold frame. They must not be replanted till late in the spring when the young growths are on the move. In the meantime the ground where they are to be planted must be well prepared by deep cultivation and manuring. Only for the purpose of increasing the stock should established plants be disturbed, as the roots are impatient of removal.

The Hardy Fruit Garden.

Pears.—Proceed with the work of pruning these when the weather is favourable. In dealing with wall trees the object must always be to have the fruit-buds as near to the wall as possible for protection. Therefore, when pruning old trees,

spurs which have been allowed to grow too far from the wall may be cut well back. The heads of bush trees must be kept sufficiently thin to allow plenty of light to reach all parts of the trees. Spurs also must be thinned if they are too numerous; it is only by this means that strong, healthy fruit-buds are formed.

Cordon Pears.—To keep these in a healthy, fruit-bearing condition, they should be lifted and root pruned every two or three years. It is only by this means that root fibres are formed in quantity, and if the trees are dealt with at regular intervals, the lifting may be done without prejudicing the following season's crop. A little chopped loam, mixed with old lime rubble and wood ashes, should be placed round the roots when replanting the trees.

The Kitchen Garden.

Turnips.—The latest-sown roots should now be lifted and placed in the store. For immediate use a quantity may be placed in a dry shed and covered with sand. The rest will keep quite well if placed in heaps and covered with ashes, but the heaps must not be made too large, or there will be danger of "heating."

Parsnips.—The bulk of this crop will keep best if left in the ground; but in case of a prolonged spell of frost, it is advisable to lift and store a quantity for immediate use.

Digging and Trenching.—This work must be persevered with whenever conditions are favourable. It is quite probable that in most gardens trenching or double digging will have to be neglected this season through lack of labour. It may also be necessary in some parts of the garden to use the plough, which would be a great saving of labour; indeed, this method of cultivation should considerably help to solve the question of labour shortage which all gardeners have to face at the present time.

E. HARRISS

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Plants Under Glass.

Early Flowering Gladioli.—Such varieties as *The Bride*, *Peach Blossom* and *Blushing Bride* should be potted in quantity, where cut flowers are in demand during the spring months. They succeed best when grown very cool, but after they are well advanced a certain amount of heat will not harm them.

Lilium longiflorum.—Any bulbs not yet potted should now be dealt with; if further delayed the growths and flowers will be weak. Cover the bulbs with an inch of soil in the meantime, so as to leave ample room for top-dressing later.

Pyrus and other hard-wooded plants, such as *Prunus*, *Lilac* and *Azalea mollis*, will now be ready for forcing. Progress will be slow at first, but constant spraying of the buds, with a steady heat maintained, will excite the plants into growth. The quality of the flowers is naturally not so good as may be expected from plants forced at a later date, but these plants give a little more variety when one is becoming tired of the long season of *Chrysanthemums*.

Lily of the Valley.—As retarded crowns become rather weak after this date, a start should be made to force the ordinary crowns. They force with greater freedom after having been exposed to severe frost. To induce a long flowering stem, shade until growth is well advanced; then admit light to get the foliage a nice green colour by the time the flowers are opening.

The Kitchen Garden.

Seakale.—As the strongest crowns are lifted for forcing, any small pieces of roots which are broken off should be preserved for stock. These pieces can be cut into lengths of 4 inches, the larger end cut straight across, and the other end cut in a slanting direction to distinguish the roots when being put in sand for propagation.

Cauliflower.—Where plants are wintering in frames for planting out in spring, abundance of air is required to keep them sturdy. In settled,

mild weather the lights should be drawn off altogether, only replacing them when rain or frost occurs. Slugs are troublesome, and must be watched for carefully.

Lettuce.—Plants growing in frames should have plenty of ventilation during fine weather. The lights should only be left on the frames during rain or frost, otherwise they are very likely to damp and thereby become spoilt.

French Beans.—More sowings should be made in pots as space becomes available. Do not overcrowd by sowing too many seeds in a pot, five or six seeds being sufficient to occupy a 9-inch or 10-inch pot. Grow in a minimum temperature of 60°, and syringe occasionally to prevent red spider obtaining a footing.

Fruit Under Glass.

Early Vinery.—This house should now be closed for starting. A little heat should be turned on, just enough to maintain a night temperature of 50°. In mild weather this can be advanced to 55°, allowing it to rise during the day as the weather may influence it. With such short days and little evaporation taking place, not much syringing or damping of the borders and pathways will be required for several weeks. Once a day will generally be sufficient, and it should be done about 11 a.m. If the Vines are young and have not yet been bent over and tied down, this must be attended to, as it greatly facilitates an even growth of the buds, providing, of course, the Vines are tied up in their proper positions when growth has sufficiently advanced.

The Hardy Fruit Garden.

Bush Fruits.—Where the ground has been properly prepared—and this should be done by trenching in sufficient farmyard manure to nourish the bushes for a long period—planting should now commence. Plenty of room is necessary to obtain the best results. All the Currants should have at least 6 feet between the bushes, while Gooseberries will do with slightly less. Being newly planted they had better be protected from frost. This can be done by placing a small quantity of decayed litter or similar material over the roots when they have been placed in position.

Fruit Room.—Pears require frequent examination, as some decay quickly and infect others if not removed. There is usually a glut of varieties in season at this date, but as they deteriorate quickly if not used when ripe, it is unwise to try to lengthen the supply by keeping them longer.

The Flower Garden.

Helleborus niger.—Flower-buds are now appearing, and if the flowers are to be kept clean, some protection from the rain will be necessary. Spare garden lights, raised on large flower-pots, will do; and where slugs or snails are troublesome a good sprinkling of sharp, gritty sand should be put around the plants as a preventive.

Early Flowering Chrysanthemums.—To avoid any risk of losing the stock by getting the plants killed by frost, the stools should now be lifted and placed in cold frames, covering the roots with sufficient soil to keep them alive until required to be brought indoors for producing cuttings.

The Wild Garden.—With falling leaves from the deciduous subjects there is a certain amount of untidiness present. Herbaceous plants, too, have finished their growth, and where this is not needed for protection the whole should be cut over. Where, however, the remains of the past season's growth are not an objection, they may be left until nearer spring, as, in some cases, it prevents a bare appearance.

Montbretias.—In most districts, particularly wet ones, these plants do not winter very well. To avoid risks, the corms and stolons attached should be lifted carefully and placed in frames, covering the roots with leaf-soil or other light soil. The lights should only be kept on during severe frost or rain. As it will be noticed how the growths commence growing during the shortest period of mild weather, it is all the more necessary to avoid coddling, which would weaken the young growths produced in spring.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

GARDENS OF TO-DAY.

BODNANT HALL, DENBIGHSHIRE.

BODNANT HALL, the residence of Lord and Lady Aberconway, is charmingly situated in Denbighshire on an eminence facing south and west, with a magnificent view of the valley and the river Conway, with the Pennine range of hills in the distance. The mansion was rebuilt about the year 1876 by Henry Davis Pochin, Esq., the father of Lady Aberconway, the present owner.

Leading from one of many terraces is the Azalea and Tiger Lily garden. *Lilium tigrinum* makes a charming autumn display, as it luxuriates here. From this terrace we approach by a flight of steps at each end the water garden or Lily terrace, some 14 feet below the croquet terrace. Here the higher wall is supported by buttresses 15 feet apart, which afford protection to more tender subjects, such as *Magnolia Delavayi* and *Acacia dealbata* (Silver Wattle), 20 feet high, a charming specimen with its silvery foliage. At the southern end of this terrace are borders planted with blue and orange shaded flowers. The corresponding borders at the north end are filled with Roses, mainly Hybrid Teas. The border on the west side of this terrace, about 18 feet wide and in crescent shape, contains yellow, orange and scarlet flowers in gradation. Quite effective, too, it is, the whole edged with *Erica stricta*, 4 feet in width. The Lily tank in the centre, becoming nicely furnished, is 120 feet by 60 feet, with a semi-circular front to correspond with the borders. On the buttress borders

are grand specimens of *Erica codonodes*, 7 feet high and as much in diameter. What a sight such specimens must be when in flower! They seed so freely, and hundreds of seedling plants have been raised from them.

A grand specimen of *Taxus Dovastonii* on the lawn attains 20 feet in height and as much as 40 feet in diameter. Clipped Yew hedges surround this terrace, and at each end openings in the hedge have been made, leading to new terraces below. Access is obtained to these by a grass promenade, 10 feet wide, from which by two flights of circular steps we come half way down to a pergola for Roses, Clematises and Passifloras, with a stone path in which herbs and flowers are becoming established. The walls on the sides of these steps contain *Crinodendron hookerianum*, *Desfontainea spinosa*, *Rhyncospermum jasminoides*, *Eugenia apiculata* and *Solanum jasminoides*, the latter rambling over the stone balustrade for about 30 feet in a glorious mass of blossom.

The walls of the lowest or Canal terrace are planted with *Lithospermum prostratum*, *Campanula garganica* and such like subjects suitable for wall gardening.

The many interesting shrubs and trees which adorn these walls and terraces I will briefly refer to *en masse*: *Mandevilla suaveolens*, *Myrtus angustifolia*, *Rhyncospermum jasminoides*, *Vitis Hendersonii*, a small form of *V. Coignetiae*; *Eugenia apiculata*, *Rosa bracteata*, very fine in flower and foliage; *Stuartia Pseudo-camellia*, 12 feet high; *Magnolia Delavayi*, which flowered this year for the first time (is this the first note of its flowering in England?); *Citrus trifoliata*, *Bignonia radicans*, *Magnolia Campbellei*, 15 feet high; *Eucryphia cordifolia*; *Abelia rupestris*, *Buddleia Colvillei*, *B. amplissima*, *B. Forrestii* and *B. rosea*; *Olearia Fosteri*, *Escallonia montevidensis*, *Hydrangea scandens*, *Tetraptera californica*, *Actinidia chinensis* (20 feet high), *Indigofera gerardiana*, *Plagianthus Lyalli*, *Viburnum odorata*, *Olearia nitida*, *Stauntonia latifolia*, *Davidia involucrata*,

planted by the late Mr. John Bright in 1876; *Abies Douglasii*, planted at the same date, 60 feet high; *Sequoia sempervirens*, 50 feet; *Abies grandis*, 55 feet; *A. Pinsapo*, 40 feet; *A. nobilis*, 60 feet; *A. cephalonica*, 55 feet; *A. bracteata*, *A. albertiana*, *A. polita*; a well-furnished specimen of *Sciadopitys verticillata*, 16 feet; an *Aralia Maximowiczii*, with four stems, fully 40 feet high and as much as 30 feet in diameter; *Acer palmata rubrum*, 16 feet high and 20 feet in diameter; and *Retinospora squarrosa*, 20 feet high and as much across, the shapely specimens of the richest golden colour I had ever seen. Bamboos and Chinese *Rhododendrons* were recently planted in bulk on the hillsides, and appeared to be a success. *Pernettyas* of the mucronata type in many colours berry freely. *Liriodendron tulipifera* was heavily laden with seed-pods. A broad herbaceous border on each side of a winding path provides flowers in profusion.

The soil seems peculiarly suited to Lilies. Some spikes of *L. giganteum*, 9 feet high, among *Rhododendrons*, were carrying two dozen seed-pods. The *Connemara Heath* (*Menziesia polifolia*) is planted in large masses with effect. A hedge of *Erica stricta*, 4 feet wide and fully 50 yards long, makes a fine sight when in flower.

Hardy Fuchsias naturally play an important part in the garden, as they generally do in north walls. Here *Riccartoni* is planted in niches on the tops of the terrace walls, where the plants droop gracefully and are objects of interest.

An interesting feature of the garden is a Laburnum-covered archway over a path; this in spring must be a bright spot. The glass, kitchen and fruit garden appears to be on a scale in keeping with the requirements of the owners.

The whole of this charming garden is in excellent condition, reflecting the highest credit on Mr. G. Gurney, who has held the post of head-gardener for the last nine years. E. MOLYNEUX.

THE MERRYWEATHER DAMSON.

FOR the last three decades I have pinned my faith to the Prune or Cheshire Damson for crop and quality of fruit, but now, on further trial of the Merryweather variety, I am forced to the conclusion that the old favourite is at last superseded; not only is the fruit larger, thus giving more flesh, but the flavour is superior. The growth of the trees, too, is much more vigorous, and, what is important, young trees come into bearing so much quicker. Standard trees planted in the autumn of 1913 have this year given good crops of full-sized fruit, so much so that I shall increase their number considerably. D. M.

BODNANT HALL AS SEEN FROM THE WATER GARDEN.
The walls are clothed to a height of 40 feet with *Pyracantha coccinea*.

Berberidopsis corallina (heavily draped with its showy flowers), *Nandina domestica* (12 feet high), *Camellia reticulata*, *Hydrangea quercifolia*, *Rubus bambusarum*, *Acacia haleana*, *Pittosporum Mayii*, *P. Tobira*, *Carpenteria californica*, *Fremontia californica* in profusion, and *Lapageria rosea*; the last named is usually grown under glass.

The Hall on the west side is thickly clothed for 40 feet high with *Pyracantha coccinea*, literally smothered with berries. *Ceanothuses* in variety luxuriate. *Davidia involucrata*, *Plagianthus betuloides*, *Edwardsia macnabiana*, in addition to *Magnolia Delavayi*, have all flowered here for the first time this year.

On the western side of the terraces is a prettily constructed ravine with a charming rivulet, each side of which is planted with alpine plants. On each side of the stream running through the Dell is the Pinetum, containing many notable specimens, such as *Cedrus atlantica*, 50 feet, and *Wellingtonia gigantea*, 50 feet—these were

SOME "W. G.'S" OF THE GARDEN.

BY THE REV. JOSEPH JACOB.

Poor old "W. G." has gone from us. Few men in their lifetime have had a longer innings of fame than Grace. Grace and Cricket have been, are, and ever will be as inseparable as Nelson and the British Navy, or Samuel Johnson and Boswell.

It is the same in the world of horticulture. There are and there have been varieties of fruit, flower and vegetable which, like the old cricketer, have held a position of singular supremacy for more than one generation of garden lovers, outliving and outdistancing many a meteoric aspirant to fame.

Such a one among Roses is the celebrated Gloire de Dijon. Raised somewhere in France in 1853 by a M. Jacotot, it, according to the dictum of one who has served his turn as the official head of Rosedom, "still remains one of the very best." I catch faint sounds of a chorus of many growers echoing "And so say all of us." For a very long time it remained in single blessedness in my own garden, and although now the Hon. Ina Bingham, Moyesii, Rayon d'Or and several others bear it company, were it ever to come to pass that necessity imposed upon me the choice of one variety only, I fancy it would be the old "Glory" that would still be there. Sixty years of fame! Where are its rivals?

It is dangerous to prophesy unless you are sure. I may be wrong, but unless I am a Dutchman I fancy that as long as Daffodils are known, the name of Emperor will be intimately associated with them. Paxton and the first Crystal Palace; Daffodils and Emperor. It is more than fifty years since its raiser, William Backhouse, sent out his new seedling. Its position in the Narcissus world has never been more secure than it is to-day. It will outlive the Merodon and it will laugh at the Fusarium as mere pin-pricks—frightening and distressing at the time, undoubtedly—but, after all, only occasional incidents in a long life of which no one now living is likely to see the end.

What, again, of the famous Ribston Pippin in pomological circles? It may be through stupid ignorance, but above all Apples it is the one that to me has a name to conjure with. How many generations of Dents have come and gone since it first fruited in their ancient Yorkshire garden? How many of the more modern ones surpass it in flavour and crispness? Can any Worcester Pearmain, any James Grieve, any Cox's Orange, or even the grand old Cornish Aromatic, or the equally old Cornish Gilliflower?

The Paul Crampel Pelargoniums round the Victoria Memorial in front of Buckingham Palace have set people thinking, and some have asked, "What is Gardening?" I answer, "That is." There is very little doubt that "Paul" is the Zonal of the twentieth century, just as in the sixties and the seventies we had Vesuvius and the celebrated tricolour Mrs. Pollock. This last was given as an offering to the magnificent bedding craze which captivated our sires and grandsires. Many will doubtless remember the sensation it caused when its raiser, Mr. P. Grieve, introduced it in 1860 or thereabouts. What talk! what writing in the gardening papers! what fashionable garden was

without it! It is still to be met with, although a more modern rival has almost eclipsed it. But it has had a lengthy innings. [We cannot agree with our esteemed correspondent that the crude blaze of colour created year after year by masses of this Pelargonium in front of Buckingham Palace is a worthy example of modern gardening. Such a sorry scheme is devoid of grace and dignity, and if this is the best that can be accomplished, we would prefer to see it replaced by verdant turf.—ED.]

Turning to Lilies; consider the long reign of the venerable white-headed *Lilium candidum*. It has been a well-beloved inhabitant of gardens great and small for three hundred years at least; how many more I must express by the algebraical "x" and leave students of very ancient gardening history to determine. It is the album vulgare of Gerard "that groweth only in gardens and hath not been declared where it is found wild by any that I can hear of" (Gerard in his "Herbal," 1597, page 39). To use the expressive title that a young curate coined when he wished to record the presence of the new Dean of Ripon at a certain clerical meeting when he was Archdeacon of Birmingham, her "Venerability" cannot be left out of the team. Queen Elizabeth in all probability had it in her garden at Greenwich. It is still "in."

I remember Mr. Bunyard, sen., telling me the history of *Gladiolus brencleyensis*; how it was raised at Brenchley in Kent in the year 1848. Very nearly three score years and ten have gone by, and it is still sold every year by the hundred. It very much looks like making its century.

Were I of epicurean tastes and able to dilate on the toothsome of Kohl Rabi or the good jelly-making properties of the fruit of *Pyrus (Cydonia) japonica*, I might have been able to talk of some culinary Pea, like Gladstone, or some Strawberry, like Sir Joseph Paxton. (Tell it not in Gath! The Director of Kew has kindly sent me some varieties of the Japanese Quince for experiments. I could not resist the recipes which lately appeared in THE GARDEN). But I have said enough, I hope, to set the ball rolling. It would be nice to hear about famous plants of past and present renown which have had "long runs" on the gardening stage. May I conclude by expressing a hope that someone with the requisite knowledge will do this and so give us something to think about as we read our GARDEN in the winter evenings. Who knows what memories and thoughts such reminders may not stir within us? Reveries! Ruminations! Perchance, the old home!

NOTES ON VEGETABLES.

IN the kitchen garden trenching the ground is not nearly enough attended to, especially in soils of a heavy, retentive nature. Trenching the soil from 2 feet to 3 feet deep not only provides a deeper rooting space for tap-rooted vegetables especially, but it warms the soil by the admission of air and conserves the moisture during a spell of dry weather in summer.

Asparagus in Beds should now have the ripened tops removed, cutting down the grass to within an inch or so of the soil. Clear away all weeds, lightly fork over the surface, and cover the bed with 2 inches of half-decayed stable manure or the spent material from a Mushroom-bed.

French Beans.—Make a sowing of five seeds of a good forcing variety—Superlative, for example—in a 4-inch pot, to be afterwards shifted into pots 8 inches in diameter. In a temperature of 65° the plants will grow freely and sturdily if placed on a shelf near the glass. Stockiness in the growth of French Beans is important for their future success.

Broccoli should now be heeled over to the north to protect the heads from frost. Take out a spit of soil on the northern side, heel the plant over, and well cover the stem with soil when taking out the spit for the next plant. The protection of the stems from frost does much to save the plants.

Globe Artichokes should have their bottom leaves cut away, admitting air about the plants. Protect this part from frost with long strawy manure.

Lettuce recently planted in frames should have abundance of air on favourable occasions to prevent the leaves damping. As fast as frames are emptied of their previous crop, fill them at once with plants from the open.

Seakale should be lifted in batches, heeling them in for a time until space in the Mushroom-house, stokehole, or in boxes under the stages of warm houses is available to continue the supply. Moist conditions with complete darkness are necessary to produce well-blanching heads.

Mustard and Cress.—Mustard should be sown every six days, and Cress every four days to give a succession. In pans or cutting-boxes sow the seed thickly, but do not cover it, and if kept moist it will quickly grow.

Potatoes.—Where the tubers were put in heaps at digging-time in various sizes, work is provided for wet weather in sorting them into sizes for use and for planting, using the small and scarred tubers for the pigs. Even if time does not permit of hand picking, the heaps should be turned over to ensure their becoming dry right through. If put together in wet weather, the bulk may cause some heating in the centre, which is detrimental to long keeping. When turned and dried, the heap should be covered with straw or bags to prevent the tubers becoming green by exposure.

E. MOLYNEUX.

A GOOD CLOSE-EATING POTATO.

ALTHOUGH, generally speaking, close-eating varieties of Potato find but little favour with the public, there still remain those who consider the ideal tuber is one which, when cooked, more closely resembles an Artichoke, or a lump of soap, than the ball of flour regarded by many as the standard by which a cooked Potato is judged.

After extended trials of many varieties, I am of opinion that none, of either coloured skin, has greater claims to the distinction of being the best among these close-eaters than International Kidney, certainly one of the handsomest varieties in cultivation, and for this reason alone still regarded as indispensable among a certain class of growers, these chiefly amateurs. Some idea of its close-eating nature may be formed when I say that out of the many hundred varieties—or so-called varieties—we have grown here during the last fourteen years, this sort stands alone, and compared with this, particularly early in the season, many recognised close-eaters among coloured varieties appear to be balls of flour.

F. R. CASTLE.

NURSERY NOTES.

MR. GEORGE PRINCE, LONGWORTH, BERKS.

THERE is a certain charm about Mr. George Prince's Rose garden at Longworth that makes it quite unlike any other Rose garden with which we are acquainted. It is situated in the midst of a very beautiful old Berkshire village some five or six miles from the City of Oxford. Most of the land in the neighbourhood is devoted to pasture and agricultural crops, and the fertile nature of the soil, which is a deep sandy loam, appears to suit all Roses, and Teas in particular, as well as it does the waving fields of Wheat which in summer-time cover many acres in this part of Berkshire. To wander up and down the long rows and hedges of Roses

is probably the best of yellow Roses for walls. It is very free and flowers over a long season.

Favourite Roses.—We have made many visits to Longworth, and there are certain Roses associated with this Rose garden that we always hope to see. Among them might be mentioned Longworth Rambler, that beautiful Noisette with cherry red blooms produced over a long season. It is very hardy and succeeds where many other rambling Roses might fail; moreover, it is nearly evergreen. Rose Fortune's Yellow, described in detail and with so much grace by Miss Ellen Willmott, V.M.H., in *THE GARDEN* for November 6, page 543, is almost as great a success at Longworth as it is at Lockinge, which, by the way, is only a few miles distant, both places being in the historic Vale of White Horse. It requires a warm situation, but is never so fine as when grown under glass. Rose species are well represented at Longworth. *Rosa sinica*,

ENGLISH *v.* LATIN NAMES OF PLANTS.

IT is really time for a firm stand to be taken against the few enthusiasts who are endeavouring to force us to substitute English for botanical names of plants. I see one suggested alternative is Whortleberry-leaved Knot Grass for *Polygonum vacciniifolium*; another, Bloody Rockfoil (it sounds like a "swear" term of endearment!) for *Saxifraga sanguinea*. Latin is not a difficult language to pronounce, and as the Universities differ in their pronunciation of it, the ordinary man may be excused for pronouncing it almost phonetically.

Let us examine the "good Old English names" themselves. Take *Saxifraga umbrosa*, for instance; this is known best as London Pride, but it is also known as St. Patrick's Cabbage, None-so-Pretty and Cheeky Johnnie, and possibly there are many other examples equally confusing. At the time the Old English names originated, the number of plants in cultivation was exceedingly small, and consequently the number of English names was correspondingly small. Honeysuckle meant one particular plant, Alysson meant *Alyssum saxatile* and nothing else; but now that almost daily we are receiving new species from all parts of the world, and there are many Alyssums with yellow, white, or pink flowers, there are not enough good Old English names to go round, and the Anglophile enthusiast must either use a mixture of English and Latin names or manufacture new "Old English" names. This sounds impossible, but, alas! it is the truth, and my apology for rushing into print is a catalogue, just issued by a well-known nursery, which I have read with amazement and alarm. It suggests in all seriousness that we should drop the botanical names, use the "true English" names—as far as they are known—and where they are unknown, or do not exist, to manufacture—"supply" is, I think, the word used—new names for them by rough-and-ready translations of their botanical names. Such a scheme, if ever generally approved, is one that should be taken in hand reverently and not hurriedly, and only by some very competent authorities.

Here are some of the results achieved by the compiler of the new English-Latin glossary. We are in future to call *Achillea filipendulina* a Dropwort Yarrow, but *Achillea Ptarmica* is a Double Sneezewort; but he also terms *Helenium striatum* a Sneezewort—a copper one this time. Again, *Armeria Cephalotes* is a Ruby Thrift, but *Armeria lauchiana* is a Sea Pink. *Heuchera zabelina* is a Hybrid Alum Root, but *H. sanguinea* is a Scarlet Saxifrage. *Mertensia echioides* is a Viper's Lungwort, *M. pulmonarioides* a Virginian Cowslip, *Omphalodes cappadocica* is a Navel-wort, while *O. verna* has the choice of three names. Similar examples are too numerous to mention, but the climax is reached with the unfortunate *Ranunculi*, for *R. Ficaria* is a Pilewort, *R. aconitifolia* is Fair Maids of France, and *R. acris* is Yellow Bachelors' Buttons. A description of a new hybrid between any two of these would be jaw-breaking enough in all conscience!

But some of these names are already fairly well known in some localities, and it is when the compiler lets himself loose on the "new names"

A HEDGE OF ROSES THALIER AND TRIER AT LONGWORTH.

in an atmosphere laden with the sweetest of perfumes reminds one of an Eastern scene where Roses are grown on a very large scale for the sake of distilling attar of Roses from the blooms. By the way, has anyone ever attempted to make attar of Roses in this country? There must be a great waste of Rose blooms year after year, especially in our large Rose nurseries. True, it is calculated to take 100,000 blooms to make an ounce of pure attar, but in the piping times of peace this is sold from 30s. an ounce upwards to even treble that price, while the smallest drop of it is sufficient to fill a large room with the delicious odour of Roses.

Not only are the Rose hedges so fine at Longworth; the rambling Roses look exceedingly picturesque clothing the dry stone walls which are a feature of this old-world village, while *Rêve d'Or*, literally smothered with deep yellow flowers, looked particularly happy and effective growing over the gable end and roof of a stable. This

the Cherokee Rose, and the variety *Anemone*, with lovely soft pink flowers, provided a feast of bloom in June last never to be forgotten.

Teas and Noisettes, with which this Rose garden has so long been associated, are beyond doubt the most lovely of all Roses. *Maréchal Niel*, still the best golden yellow Rose in cultivation, is a great success on a warm border; while *Princesse de Sagan*, *L'Idéal*, *General Schablikine*, *Lady Roberts*, *Medea*, *Mrs. E. Mawley*, *White Maman Cochet*, *Souv. de S. A. Prince*, *Mrs. Foley Hobbs*, *Mme. Constant Soupert* and *Harry Kirk* are to be numbered in the *élite* of the Rose family. It is only fair to Mr. Prince to mention that his successes in the leading classes for Teas and Noisettes at the National Rose Society's exhibitions and at other important Rose shows have been quite unique, although no one would welcome keener rivalry in these classes more than Mr. Prince, who has the successful cultivation of all Roses so very much at heart.

that he helps us to appreciate this Anglophile movement at its full value, for in the process of the translation many of the plants almost completely lose their identity. Thus, *Campanula pulloides* is a seedling of *C. pulla* and its name surely implies pulla-like, but we are to call it Dwarf Purple Bellflower. Again, *Saxifraga scardica* is to be Macedonian Rockfoil, notwithstanding the fact that there is already a perfectly distinct *Saxifraga macedonica* in cultivation. From these examples the reader can judge what the Anglophiles would let us in for, solely in order that, by their adoption, we may be able to drop the botanical names; but can we? Even after we have striven to learn all the local nicknames of the unfortunate plants, in order that when we want an *Achillea* we may, by ordering a Sneezewort, really get an *Achillea*, and not, as seems equally possible, an *Helenium*, is it possible that we can do without the hated botanical names? I fear not, for unless we are to be at the mercy of any unscrupulous supplier of plants, it is always necessary for us to know the botanical names in order to check what we are getting and to compare prices.

It must be borne in mind that very large numbers of the plants we cultivate in our gardens come from abroad—Holland, Japan, Switzerland, and nearly all mountainous countries supply us—and if we know the botanical names of our plants, our path is smooth, as the botanical names are the same in every country. It is useless for the Anglophiles to cumber us with hundreds of newly manufactured "English" names for the sake of preserving the few "good old" ones (which, by the way, include such charming names as Bugwort, Lousewort, Liver-wort, Pilewort and Fleabane!), when it is quite clear that we must know the botanical names as well.

There is a certain amount of hardship, no doubt, in setting out to learn the botanical names, when one is not used to them, and I disliked doing so as much as anyone, but I soon recognised the necessity, as my garden grew, of knowing the names of its inhabitants, and as new plants, bearing only botanical names, came in I soon realised that it was hopeless to try to remember a mixture of English and Latin names. I have for some time given up the unprofitable attempt. This is a practical age and one's time is very fully occupied. To ask us, therefore, to spend it in learning Old English names and acquiring newly manufactured ones is to compel us merely to waste it, for they are, and must increasingly become, as useless to us for our general knowledge of plants as Erse would be to us for general purposes of conversation.

MURRAY HORNIBROOK.

OUR SUPPLIES OF FERTILISERS.

THE President of the Board of Agriculture and Fisheries has appointed a Departmental Committee to make arrangements with a view to the maintenance, so far as possible, of adequate supplies of fertilisers for the use of farmers and gardeners in the United Kingdom. The committee is constituted as follows: The Right Hon. F. D. Acland, M.P. (chairman); Mr. R. H. Rew, C.B., Mr. T. H. Middleton, C.B. Mr. G. J. Stanley, C.B., C.M.G.; Mr. J. Dundas White, M.P.; Mr. H. Ross Skinner; Mr. E. J. Foley; and Mr. R. J. Thompson. The secretary is Mr. H. D. Vigor, 3, St. James' Square, London, S.W.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

VARIEGATED WALLFLOWER (J. S.).—Such variation is not uncommon; incidentally, too, the plant is of little value. Being a growth sport, it could only be perpetuated by means of cuttings, and in all probability these with cultivation would revert to the normal condition. Of no commercial value, it is entirely optional whether you consider the variety of sufficient interest or merit to attempt to increase it. You say nothing about the colour, but, should it prove to be a yellow-flowered variety, we should not consider it worthy of increase. If more striking in the plant than the leaves you send suggest, it might prove attractive grown for leaf effect only. To do this, all flowers would have to be suppressed and the plant increased by means of cuttings, those preferably with a heel. For such cuttings August and September are the best times.

PLANTS FOR TOWN GARDEN IN MAY (W.).—You might with advantage plant such subjects as *Anemone sylvestris*, *Saxifraga cordifolia* purpurea, *S. Clibrani*, *S. bathoniensis*, *S. Miss Willmott*, such *Aubrietias* as *Dr. Mules*, *Lavender*, *Souvenir de W. Ingram*, *tauricola* and *Prichard's A 1*, *Alyssum saxatile compacta*, *Phloxes verna*, *amona*, *atropurpurea* and *Vivid*, *Veronica gentianoides*, *Trollius asiaticus*, *T. Orange Globe*, *Primula cashmeriana*, *Hepstias* in red, white and blue, *Iris pumila*, *I. p. cerulea*, *I. nudicaule*, *I. germanica violacea*, *Mrs. Darwin*, *Queen of May* and *Princess of Wales*, *Aster subcaeruleus*, *A. salsuginosus*, *Dielytra formosa*, *Campanula muralis*, *Anemone Pulsatilla* and *Adonis amurensis*. Single and double *Pyrethrums* would be good, though May is early for them. They are quite useful in early June, and so are the Spanish Irises, which are both beautiful and cheap.

VARIOUS QUESTIONS (J. V. H.).—Any of the soil fumigants should help to get rid of the pest to which you refer. The soil fumigants would be best applied any time when the land is vacant. The named *Antirrhinum*s would have been best perpetuated by means of cuttings inserted in boxes or pots in September, though you may still do so. The chances of successfully rooting the cuttings now are, however, less than six weeks ago. Failing the cuttings, shorten the old plants back slightly, and lift and frame them for the winter. Your plants appear to be of the tall type, and in a wind-swept garden it may be necessary to stake them. If of the tallest-growing type, the plants will still incline upwards in spite of pinching. You do not say the size of the bed for which you require the herbaceous plants; hence, rather than give you any haphazard selection, we would prefer that you repeat that query with the particulars named, in order that a useful list of subjects might be given. The name of the plant sent is *Dielytra exima*.

THALICTRUM DIPTEROCARPUM (Aron).—This plant is hardly likely to be a permanent success in heavy soil, and is better suited to a moderately rich, light mixture of loam and leaf-soil. At the same time it prefers a rather cool root run. It might be well in your case to pot it for the winter and prepare a position on the above lines for planting in March or April next year. The best time to deal with the Red-hot Pokers is March; they may then be divided freely. They prefer rich and deeply cultivated soils. From your description we should suspect that the *Montbretias* have suffered from disease, though this is usually kept in check by annual lifting. Do you, however, replant in the same ground each year? If so, you are courting failure. Dry stored corms should be planted singly in early April in sweet, fresh loam, employing a score or so a few inches asunder to form a group. If you could obtain a little chalk or lime, mingle this with the soil a month or so before planting.

THE GREENHOUSE.

PLANTS FOR A VESTIBULE WALL (E. M. W.).—We are doubtful whether there is sufficient light for flowering climbers to succeed under the conditions indicated by you. The most likely subjects are *Abutilons*, especially *Golden Fleece*, but perhaps as the wall is coloured white you would prefer a crimson kind, in which case *Sanglant* is a good one. The white-flowered *Solanum jasminoides* might thrive there, and, if so, its flowering extends over a lengthened period. There yet remains

one more subject which would perhaps give you satisfaction, namely, *Hibbertia dentata*, whose yellow flowers are borne during the first three months of the year. The slender, twining shoots are clothed with ovate leaves from 4 inches to 5 inches long, and of a pleasing bronzy green tint that should be very conspicuous against the white background. The young leaves and points of the shoots are tinged with crimson. Foliage plants that would thrive there are the climbing forms of *Ficus*, namely, *Ficus repens* and its smaller variety *minima*, with the larger-growing *Ficus radicans*. These would clothe the wall with a dense mass of small, deep green leaves, but no flowers.

BEGONIA TO NAME (R. L. S.).—The Begonia specimen is such a poor one that it is impossible to name it with certainty. We, however, have but little doubt that it is *Begonia Corbeille de Feu*. The derivation of the word *Calliopsis* is from the Greek—*Kallistos*, most beautiful; and *opsis*, an eye.

TREATMENT OF GESNERAS (J. A.).—As the Gesneras go out of flower less water is needed, and they will then go gradually to rest. When dormant the soil should be kept dry, but not allowed to become parched up. By February they will be ready to start into growth, when they may be potted into small pots, shifting them into larger ones when necessary. You ask if they can be wintered in a cool greenhouse, which is such an elastic term that it is difficult to answer. In order to keep Gesneras in a satisfactory state during the winter, they should be in a structure with a minimum temperature of 50°. When they start into growth, more heat will be beneficial. They may be wintered in the pots they are now growing in, or, in order to economise space, they can be shaken out and laid in boxes of fine soil. This, however, should not be done till they are absolutely dormant.

ADVICE ON CRINUM MOOREI (A.).—*Crinum Moorei* will sometimes push up more than one spike from a bulb, and as yours gets stronger it will probably do the same. A height of 4 feet is not unusual for the flower-spike to attain, but this is a feature which depends to a certain extent upon the situation of the plant. If it develops under glass, particularly if at all shaded, the flower-stem is sure to be taller than if it is outside in the open air. You may, if you wish, remove the offsets when the plant is repotted, which is best done in early spring, before growth commences. On the other hand, the plant may be shifted into a larger pot or tub and the offsets allowed to grow unchecked. In this way the *Crinum* in question will form a mass or clump, from which an increased number of flowers may reasonably be anticipated. In the case of these established clumps, annual repotting is by no means necessary. In that case, when the pots are well furnished with roots, an occasional stimulant during the growing season will be beneficial. We are very pleased to learn that you have had such success with this *Crinum* by following our previous advice.

ADVICE ON BEGONIAS (W. F.).—We presume that the Begonias referred to by you belong to the tuberous-rooted section. If so, they will be soon going to rest. When quite dormant they must be kept almost dry. Large or fair sized bulbs may be wintered without any water, but as, in all probability, yours are very small ones, they are likely to perish if parched up. For this reason a little water may be given occasionally, but not sufficient to keep the soil nearly as moist as if the plants were in a growing state. They must be wintered where quite safe from frost. By many, tuberous Begonias are, when dormant, laid on their sides and stored underneath the stage of the greenhouse. This practice does not permit of their condition being readily ascertained, so that as your little plants need careful attention as regards water, they will be best given a good position on the stage. In March, by which time the tubers will be on the point of starting into growth, they may be shaken clear of the old soil and repotted into small pots. A mixture of equal parts of loam and leaf-mould, with a good sprinkling of sand, will suit them well. In potting, the tuber should be buried just below the surface of the soil. Directly the roots take possession of the new compost, the plants must be shifted into larger pots, as if allowed to become pot-bound their growth will be checked.

TREES AND SHRUBS.

FASCIATED SHRUB TO NAME (H. T.).—The shrub sent for identification and examination is not *Azara microphylla*, but *Cotoneaster microphylla*, and the branches are in the condition known as fasciated. This condition is often noticeable in plants that are growing vigorously, excess of vigour apparently inducing an abnormal number of adventitious buds, which in trying to develop cause the fused-like appearance of the branch. The same thing may often be noticed in the flower-spikes of *Lilium auratum*. Under normal conditions an extra number of branches should be formed instead of the fusion in the fasciated state.

HARDY FUCHSIAS (S. W.).—The Fuchsia sent for examination is *F. macrostemma*, a native of South America. It is quite natural for the flowers to be borne in the manner described, and nothing can be done to make the plant more attractive at flowering-time. If the shoots were staked up, they would look unnatural. The best outdoor Fuchsia is *F. Riccartonii*. This forms a bush 6 feet to 10 feet high in the South-West Counties, and would probably grow into a fine bush with you, especially if the branches were protected in frosty weather with Spruce branches or a little Bracken. The most critical period is the first few years, before really hard wood has been formed. The flowers of this plant are conspicuous when in their natural position.

THE GARDEN.

No. 2298.—VOL. LXXIX.

DECEMBER 4, 1915.

NOTES OF THE WEEK.

An Entrance Fee to Kew Gardens.—The New Year will in all probability bring an important change to the nation's gardens at Kew. For the first time in the history of these gardens an entrance fee, not yet fixed, is to be exacted. We much regret that such a step should be taken, and, apart from the principle, it seems very doubtful if sufficient revenue will be reaped to pay the cost of installing turnstiles and working them. What a hue and cry there would be if a charge were made to enter Hyde Park; and yet in principle it is much the same.

Perpetual-Flowering Carnation Society.—Quite a good exhibition is anticipated at the Royal Horticultural Society's Hall on Wednesday, December 8. In addition to the conference in the afternoon, a further attraction will be the ladies' flower stall, where flowers and plants will be sold for the benefit of the Royal Horticultural Society's War Horticultural Fund. Wounded soldiers and all members of the Overseas contingents will be admitted free.

The White Pine of Mexico.—As a lawn or park specimen this Mexican Pine forms an effective and graceful tree suggestive of *Pinus excelsa*. A tree in the conifer collection at Kew is very attractive with numerous cones at the present time. It is a five-leaved Pine, the grey-green colour of the leaves being very effective on a carpet of grass. *Pinus Ayacahuite* was first introduced in 1840 by Hartweg, who sent home seeds to the Royal Horticultural Society. In its native habitat it reaches 100 feet in height. There are a number of good specimens of *Pinus Ayacahuite* in this country, mostly in the South and West, and the largest are between 60 feet and 70 feet high. The cones are about a foot long, usually slightly curled at the apex.

Produce of Crops, 1915.—From the official preliminary statement showing the estimated total produce and yield per acre of the Potato and root crops in England and Wales in the year 1915, we note that the average yield of Potatoes per acre in England and Wales is estimated to be exactly equal to the average of the preceding ten years; while the total production, although nearly 100,000 tons below that of last year, is some 180,000 tons above the average. Turnips and Swedes have produced less than in 1914 by some 1,644,000 tons, mainly owing to the reduced acreage, although the

yield per acre is also a little below that of 1914 and about two-fifths of a ton below the average.

Tulip Bread.—Paragraphs have lately appeared in some of the daily papers to the effect that owing to the scarcity of corn in Holland and to the difficulty in disposing of the usual number of Tulip bulbs, they have been used to help out the flour in bread-making. When Tulips first came to Western Europe, they were regarded as

sent a hundred bulbs (*c.* 1601-2) to an apothecary in Vienna to be candied.

A Culinary Raid.—When in quite modern times Duc van Thol Tulips became so abundant that they could not be sold, a certain grower in the neighbourhood of Haarlem made an attempt to eat them as food, but declared he could not manage them. The narrator of this episode significantly adds, "perhaps he did not have the

proper recipe for their preparation and cooking." Hence Tulip bread in 1915 will not be the first occasion on which the good people of Holland have made a culinary raid upon the Tulip.

Southampton Royal Horticultural Society.—At a Council meeting of this society, held on November 23, the finance committee presented a report and accounts, showing a deficit on the year's working of between £3 and £4. The Council are to be congratulated on carrying through their programme of three excellent shows, paying all prizes in full, besides giving donations of five guineas to each of the horticultural benevolent institutions. At the recent Chrysanthemum show most of the exhibits were sold in aid of the Southampton Division of the British Red Cross Society, whereby the Council handed over a cheque for £31. A special meeting of this horticultural society is to be held shortly to consider the programme for next year.

A Handsome Gift of Rose Trees.—Owing to the kindness of nurserymen, the Croydon Horticultural Society has been able to add a large number of Rose trees to the Parkhill Recreation Ground. New and up-to-date varieties were given; about ten dozen presented by Mr. George Prince, Oxford; about eight dozen presented by Messrs. Frank Cant and Co., Colchester; about six dozen presented by Mr. Thomas Butcher, Croydon; about two dozen presented by Messrs. Prior and Son, Colchester—a total of over 300 Rose trees in all, the only condition being that one

small, unobtrusive label should be placed in each bed stating the name of the variety of Rose and the name of the donor. In these times generous actions for the benefit of the public should be fully recognised. We hope that the trees will do well under the care of a small sub-committee that has been appointed to look after them.

CONES AND LEAVES OF *PINUS AYACAHUITE*, THE WHITE PINE OF MEXICO.

potentially edible. The merchant of Antwerp who received a cargo of Tulip bulbs from the East in 1562 promptly sampled them with oil and vinegar, thinking them to be a new kind of Onion. The rest of the bulbs, with the exception of a lucky few that he gave to George Rye of Mechlin, he planted in his kitchen garden. Even Clusius, although he knew their value as flowers,

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Antirrhinums Eaten by Animals.—I have read several notes lately about Antirrhinums eaten by animals, and I would like to give readers of THE GARDEN our experiences in these gardens. We have a long border of Antirrhinums each year, Crimson King in the back lines, Pink in the centre lines, and Yellow Prince next to the path. Our trouble for the past two years has not been mice, but tame pigeons picking off the flowers of Yellow Prince, not touching those of any other colour. I should be pleased to know if any readers have had the same trouble.—O. W. TRILL, St. Leonards Park Gardens, Horsham, Sussex.

Lapageria rosea alba.—It is worthy of note that *Lapageria rosea alba*, the white form of the species so beautifully portrayed in your issue for November 20, page 567, has not been in cultivation so many years as might at first be imagined. During the time that the late Mr. William Bradbury Latham, who died less than a year ago, was at the Jardin des Plants in Paris, the only plant in Europe of the white *Lapageria* was under his charge, and Mr. Latham was fond of recording how he believed he saved its life. The plant had been sent to Paris with instructions that the soil in which it grew was of a marly nature, and in such a soil the *Lapageria* had been planted, only to eke out a sickly and dwindling existence. Mr. Latham had, however, early learnt the valuable lesson that plants which in Nature might grow in a particular kind of soil did not always succeed in the same kind of soil when placed under cultivation; and he persuaded his chief to let him wash it out of the marly soil and pot it into rough peaty soil with plenty of sand and crocks, following which the plant grew luxuriantly.—K. G. J.

Scabiosa caucasica.—I was very pleased to see the article on this hardy perennial in THE GARDEN for November 13, page 556. Although the writer speaks at length on the cultivation of *Scabiosa*, he omits to mention one or two points in its favour. For the benefit of amateurs residing at the seaside I must mention that it will grow strongly there; moreover, in sunny positions and in light soils of gardens near towns it thrives splendidly. Its flowers are magnificent for cutting, for they last very well in vases. Your writer does not mention these three points, which are, I think, rather important. We must thank him for giving us the useful cultural details, which will be extremely helpful to many; but in our exposed district we are not successful in raising this plant by the early autumn sowing he advocates. We find it better to sow in a frame in the early summer, and prick out into good rich soil as soon as we can. When the winter comes on, we lift our seedlings, which are now strong plants, and put them in a cold frame for the winter, planting out in March. We find we get splendid plants by this method. The writer of the article speaks about the deterioration of the size of the flowers. We have found that this is remedied by keeping the soil rich, or fairly so, and giving a good position in the sun; also, every second or third year the plants have to be taken up and divided, only the strong portions being then returned to the soil. We do this in the spring or the autumn. *Scabiosa*, when once established, flowers here from June to September. It is a

plant that everyone should grow, for its large "pincushion flowers" are an acquisition to any perennial border.—E. T. ELLIS, Weetwood, Ecclesall, Sheffield.

An Iris Walk of Eastern Splendour.—The Iris borders in the accompanying illustration form a part of a large colour-scheme made some seven or eight years ago. There are fruit trees on either side of the grass walk. The Irises grow between the trees, and in front of them there is an edging of yellow *Violas* (Bullion), which are in full flower at the same time as the Irises. The

BORDERS OF PALE BLUE IRISES IN A READER'S GARDEN.

name of the Iris is *germanica Celeste*, a lovely shade of lavender blue, which, together with the *Viola* mentioned above, gives a very attractive and pleasing effect. The trees provide just enough shade for the plants, and, by keeping the ground nice and moist, the flowering period, both of the Irises and *Violas* is prolonged. I might say that in the spring, as soon as growth commences, we give the Iris clumps a slight top-dressing of light soil, and so keep them in good health. It may be of interest to state that this successful colour-scheme had its origin in a Roumanian garden some twenty miles from Bucharest. After a dusty and exciting motor ride, taken at a speed much beyond our British limits, over roads far from smooth, a small party of Londoners reached their host's country house, and on entering the fine old garden, hidden behind high outer walls, feasted their eyes upon a glorious border of pale blue Irises fringing the orchard in bold clumps of colour that matched the cloudless sky. One of these travellers, having a garden in the making, resolved to appropriate and transplant the idea to Surrey, and he has never regretted doing so.—W. COLES.

Actinidia chinensis.—I was interested to read the note of Mr. James McGran, in your issue of November 20, saying how successfully he had grown *Actinidia chinensis*. I have twice tried it here on a pergola with a south-west exposure, but have failed with it miserably each time. I fear it cannot withstand the droughts we have. Will Mr. McGran kindly say the aspect his plant

has? Mr. E. H. Wilson has, I believe, stated that *Actinidia chinensis* in its native habitat grows 40 feet or more high through trees. I have no idea of approaching this height, but it is so beautiful that I should much like to get it to grow sufficiently to cover a few feet of a pergola. Does Mr. McGran grow his plant on a wall, or where?—B., Weybridge.

Eucalypts for English Gardens.—I cannot quite agree with you (issue November 13, page 552) when you say that the more rounded leaf is immature, and that the dark and sickle-shaped

one is the final. I think—from a good deal of observation which I have made in the South of France and in the few trees which I have seen in England—the shape and colour of the leaf have a great deal to do with the nature of each tree; also the time of the year when the tree is putting out new leaves. There is a tendency in the spring to throw out blue, rounded leaves, which change as the summer goes on, especially in young trees, into the sickle-shaped and harder leaves. The tree grows more in the month of September, if the weather is favourable, than any other month in the year. Round leaves will appear each springtime on an old tree quite high up; for instance, the old trees growing against the walls of the hotel at Ilfracombe is a case in point. I have two trees here in my garden, planted the same time from the same seed. One has round leaves with but few sickle-shaped ones; this tree had the head blown off last October. This summer it threw out another runner, leaves round; it is now about 15 feet high. I planted out each tree three years ago. The other tree, growing within 2 yards distant, has had from its earliest growth very few round leaves; it is 20 feet high and densely covered with sickle-shaped leaves of a hard and dark colour. Both trees are, of course, *E. globulus*. Another tree, a fine specimen about 25 feet to 30 feet high, planted out four years, stem circumference 15 inches, has some fine round leaves on the lower branches, which I would call thoroughly mature leaves, at least four years old; the tree thickly covered in sickle-shaped leaves from

about 12 feet upwards. Unfortunately, it is forked from about 20 feet high, and I topped it early last September. Since then it has thrown out a large quantity of sickle-shaped new growth. Last September I saw the two finest trees of *E. globulus*, I fancy, in England: one at Kingswear, Dartmouth, and one at Paignton, the latter a noble, beautiful specimen tree, which I was told was fifteen years old. There is also a good tree at Torquay in the shelter of the Rock Walk. I have, through the kindness, I think, of your correspondent Mr. Bowles, a number of different Eucalypts growing in my garden, but, unfortunately, my then gardener mixed up the young plants, and I am unaware of the names of the different species. One which I believe to be *Gunni*, planted out four years, flowered well this autumn, a similar, though smaller, blossom to *E. globulus*. This tree is straggly and scraggy, but is at least 20 feet high. *E. amygdalinus* has done well in my garden.—W. A. BATTERSBY, *Frefans Bournemouth*.

[The foregoing letter was sent to Mr. E. A. Bowles, M.A., F.L.S., from whom we have received the following reply:

"In using the word 'mature' the intention was to follow the use of the word in J. H. Maiden's 'Critical Revision of the Genus Eucalyptus,' the latest and most authoritative voice on the subject. There the leaves from mature, *i.e.*, flowering shoots are always described as 'mature leaves.' It is true he uses 'juvenile leaves' as the opposite; that is to say, for foliage growing on shoots not yet branched into mature and flowering form. Juvenile and immature therefore mean—not what Mr. Battersby takes them for in this note, leaves of more than one year old, whether on growth shoots or flowering shoots—but those leaves produced on the branching portions of the tree that are ready to form flower-buds. The large globulus on the Ilfracombe Hotel illustrates this point well; for, whenever it has had to be trained back, the strong *unflowering* shoots that are thrown out to replace the growth revert to the juvenile or immature forms with rounded leaves, just the same as old Holly, or sometimes *Colletia cruciata*, if cut in hard, will produce the juvenile form again on the strong shoots thrown out just above the injury. A Mulberry also produces deeply cleft immature or juvenile leaves when cut in hard to old wood. *Gaya Lyallii* also, and many other trees with two forms of foliage, might be cited as so doing. The globulus Mr. Battersby refers to as having its head blown off, of course in its new growth reverted to the immature form of leaf; and the other tree with fine round leaves of four years old, naturally enough, has them on the lower branches, that is where they were formed before the tree branched out into the mature sickle-shaped leaves. Reference to Maiden's work would show that it is a general rule for the juvenile leaves of Eucalypts to be rounded, and, in those species that have a mature form of foliage, to be long and narrow and frequently sickle-shaped. *E. cordata* seems to be the only species that we can grow in England which retains the juvenile rounded leaves on flowering branches. *E. pulverulenta* sometimes does, but a tree supposed to be that species at Myddelton House, Waltham Cross, has in the last two seasons produced a second form of leaf on its topmost branches. If Mr. Battersby were to prune severely any portion of his tree with only sickle-shaped leaves, cut it back to stout wood, that is,

it would be as certain to bear rounded leaves on the shoots made from the stump as a cat is to yowl if you tread on her tail; and whenever portions of an old tree have been broken by wind or killed back by frost, round leaves are likely to appear on the strong shoots made to repair the injury. These bluer and rounder leaves of *E. globulus* are so much more beautiful than the dull-coloured, sickle-shaped ones that where several trees are grown it is worth while to prune one back every spring to obtain the blue leaves in abundance. Eucalypts of many species have set flower-buds with great freedom this season, but it seems so probable that the one-in-ten-years' Eucalypt-killing winters is upon us that it may be a case of immature leaves for all of us next year."—ED.]

APPLE LANE'S PRINCE ALBERT.

IN THE GARDEN of November 20, page 565, Mr. H. Turner does well to draw attention to the merits of this Apple, as it is certainly one of the most useful of culinary varieties, and during six seasons' experience in a Gloucestershire garden I have not known it fail to bear a satisfactory crop. The trees require special care in their management, as the growth is very spreading in habit and is not too vigorous. They come into bearing at an early age, and some thinning of the fruit is often necessary, otherwise young trees are liable to have their growth checked, which should be avoided, if possible. On the

BRAMLEY'S SEEDLING, AN INDISPENSABLE COOKING APPLE.

whole I think this variety is more satisfactory as a bush than a standard, and trees that bear full crops should be liberally fed to get the best results.

I find that with us Bramley's Seedling is a better Apple, as it is a more vigorous grower and a particularly free cropper. This year it has proved the best culinary Apple in the garden as regards cropping, and while some varieties were attacked by blight early in the season, Bramley's Seedling escaped untouched. Our orchard trees of this variety were a perfect picture

before the fruits were gathered, and some bushes planted four years ago carried splendid crops, some of the fruits weighing 1lb. each. If I could grow only one cooking Apple, I should choose Bramley's Seedling. If young bush specimens are inclined to be too vigorous after they have been planted two or three years, lift and replant them; this will promote fruitful growth and assist them to crop freely.

J. G.

THE ORIGIN OF THE LOGANBERRY.

BY EDWARD A. BUNYARD, F.L.S.

THE Loganberry is an excellent example of a fruit of uncertain origin for which, when it goes out into the world, it is deemed necessary to provide a respectable parentage. In this case tradition has provided, as in a recent note in THE GARDEN, two forbears of the highest respectability—the Blackberry and the Raspberry. The evidence, however, on inspection fails to substantiate this claim, and the parents cannot, I fear, be termed other than putative.

The known facts are these. Judge Logan, wishing to try all available Raspberries, Blackberries and Dewberries, collected in his garden at Santa Cruz a large number of these fruits.

In close proximity were plants of (a) a Dewberry Auginbaugh (a descendant of *Rubus vitifolius*), (b) Texas Early Blackberry (*R. villosus*?), and (c) a Raspberry (*R. Idæus*), name uncertain, but resembling Red Antwerp. From this *ménage à trois* sprang the Loganberry. The only certain fact is that the mother was the Dewberry. The pollen parent *may* have been one of the neighbours, or, equally, any of the other Rubi in the garden.

It is regrettable to pry thus into a family history of some delicacy, but science knows no scruples.

The experimental method will alone solve this interesting point.

It is worthy of remark that, so far as my experience goes, seedlings of the Loganberry come quite true. Judge Logan found otherwise. His seedlings, while true in growth and habit, were often inferior in fruit. None, however, was found to revert to one or the other parent, thus keeping the secret of their origin. It is, therefore, quite possible that the Loganberry may be a mutation and not a cross at all.

DRY-WALL GARDENS.—I.

A PART from an extensive rock garden, nothing creates greater pleasure than a dry wall planted with rock plants. The occupants simply revel in these conditions, losses are rare, expansion is healthy and prodigal, upkeep is neither great nor laborious, and the floral effect transcends efforts that in other directions are often

The wall built on the ledge system commends itself most for arid counties. Whatever type is selected, the stones should be laid firmly, the joints be carefully filled with soil, and all vacant spaces behind filled up and made thoroughly firm as building proceeds. The soil used should be a good loam, with plenty of grit and a quantity of old crushed mortar rubble or chalk added, as practically all free-growing alpine will grow in this compost, the most notable exception I can call to mind at the moment being *Lithospermum prostratum* and its forms, which detest lime.

Planting Dry Walls.—This should take place when building. In this way larger plants can be used, and it enables the roots to be carried well back into the soil behind. These should not be huddled up, but be spread out to their fullest capacity, so that a large body of soil is thus open for their activities. The crown of the plant in every case should come close up to or within the face of the wall at the time of planting.

The type of plant that succeeds best in dry-wall planting is worth considering, as so much of this

them over morning and evening with clean water; then, later in the season, should a period of drought come, water in copious quantity may be necessary. This is readily applied through a fine rose of Haw's pattern, attached either to the water-pot where the area is small, or inserted in the garden hose where it is extensive. The water must be kept continually on the move, so as not to wash the soil from the joints. It may, however, be noted that watering is rarely necessary with plants in established walls, and should only be resorted to when the plants begin to exhibit clear signs of distress.

In the method of arranging plants in dry walls there is ample scope for artistic taste, and here it is that picturesque combinations of leaf and flower produce endless pleasure and admit of variations to which there is practically no limit.

Coombe Court Gardens.

THOMAS SMITH.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Lælio-Cattleya Alex (*Lælio-Cattleya* Tunis × *Cattleya aurea*).—A remarkably beautiful and distinct hybrid, having salmon-coloured sepals and petals, and rich crimson, heavily frilled lip. Shown by Messrs. Stuart Low and Co., Jarvis Brook, Sussex.

AWARDS OF MERIT.

Lælio-Cattleya King Manoel.—The parentage is unknown. Sepals and petals coloured reddish orange, the rich crimson lip being conspicuously blotched with yellow near the throat. From J. Gurney Fowler, Esq., Pembury, Kent.

Cypripedium Swallowtail (*C. fairrieanum* × *C. Mrs. Qeburt*).—The dorsal sepal of this beautiful variety is white, heavily spotted chocolate, and with brown slipper or pouch.

Cypripedium Iona Priory Variety (*C. bellatulum* × *C. fairrieanum*).—In dwarfness and habit this shows the influence of the first-named parent. Dorsal sepal white, heavily spotted and lined crimson; lip brownish crimson. A very interesting hybrid.

Cypripedium Priory Beauty.—A Lord Tankerville hybrid, the handsome broad white dorsal sepal copiously spotted blood crimson, the incurving sepals and petals being reticulated with brown. These three beautiful novelties came from Mr. R. Windsor Rickards, Usk Priory, Monmouthshire.

Carnation Louvain.—Quite a good and attractive shade of cerise with salmon. The variety is sweetly scented. Shown by Mr. A. F. Dutton, Iver, Bucks.

Chrysanthemum Louisa Pockett.—A giant white Japanese, in all probability one of the largest yet seen. From Messrs. W. Wells, Limited, Merstham.

Chrysanthemum Aristocrat.—A so-called "single" with half a dozen rows of florets. The colour is yellow.

Chrysanthemum Monica Mitchen (Single).—The florets are coloured red, the disc yellow. These two were shown by Mr. Norman Davis, Framfield, Sussex.

The foregoing novelties were exhibited before the Royal Horticultural Society on November 23, when the awards were made.

A WALL GARDEN IN THE MAKING.

more costly. Then, the actual work of creating such a garden is well within the scope of everyone who delights in laying out and arranging their own garden. The best constructive material is stone, although with patience and skill brick may also be made to answer. A good stone for plant life should neither be too hard nor too soft, the latter especially being avoided, as it is sure to disintegrate under the action of frost. If the edges are fairly square, so much the better, as then the stone is easy to lay, and it enables copious ledges and joints to be arranged with ease and certainty. It is important to observe, in laying the stones, that the edge buried in the wall should be slightly lower than the exposed edge; in this way water striking the face will percolate behind to the roots. A wall built on this system recedes sharply away from the ground level. The incline or "batter" in this case may be as much as 6 inches in every foot of height obtained. In an upright wall the set-back or "batter" need only be 2 inches to every foot of height.

material can often be produced at home. After much experience in this and allied work, I can affirm that permanent success is much greater from the use of small rooted cuttings and seedlings than from plants that have become root-bound in pots. The former are also the most certain and easily managed where a dry wall has to be planted after building, or for making good any vacancies in established walls.

The season for building dry walls extends from October till March, it being possible to carry on the work at any moment when the soil works free. When very wet or in a pasty condition, the work of building should be suspended, as soil put together in this condition shrinks considerably when dry, and this opens a way for air to penetrate into the wall, to the ruin of the plants.

After planting is completed, little further attention is necessary. With drier conditions in March, growth will become active, and about this time it is to the advantage of the plants to dew

NOTES ON AURICULAS.

IT has been stated that the two most critical months for the Auricula are November and December, but the amateur need have no fear on this score if he just gives the plants a little extra attention and keeps them as dry as possible overhead. Plenty of air must be admitted at all times, and this will help to maintain the plants in a healthy condition. During the months referred to very little water at the base will be needed; but if the weather continues congenial and no sharp frosts occur, it will be necessary to look through the collection about once each week to see if they need water. At this season great care is required in regard to giving water. Each example should be studied to prevent overwatering; while, on the other hand, it must not become dust dry. Both extremes are detrimental to the well-being of the Auricula. No water must accumulate in the heart of the plant, or the stem may decay. Some of the lower leaves will turn yellow, and these must be removed directly they will readily part from the stem. If severe weather, is experienced, the frames may be closed at night and a mat or two placed over the lights for protection. This, however, is not really necessary, and no harm is done if the plants are frozen at this stage; but, if possible, I always try to keep the frames frost-proof.

Autumn Bloom.—A correspondent has raised the question of autumn bloom; that is, a few plants push up a spike out of season. No doubt this happens in every collection; at least, I get a few, and it does not appear to make any difference to the spring crop. The buds are pinched off as they develop, and the stem is allowed to die gradually; but a watch is kept for disease at the base, and, at the first sign of any damp, a little powdered charcoal or lime is sprinkled over that part of the plant.

Cleanliness.—This is absolutely essential with all plants, and Auriculas in particular. Green fly is sometimes troublesome, but it is easily destroyed by lightly vaporising the frame directly any is seen. It is occasionally advised to use a brush, but this method is never effective, and it is also a waste of time in these days when so many reliable fumigants can be procured at such a cheap rate. At this period of the year the collection should be looked over and each plant examined. All weeds and mossy substances on the soil must be removed. Dirty pots may be scrubbed, and the plants rearranged so that each has ample space, and then the

whole batch will present a smart and clean appearance.

Seedlings.—In a previous article I advised sowing the seed directly it was ripe, and where such work was carried out, some will have germinated and formed two or three tiny leaves. These should be pricked off about an inch apart into pans of rather light soil, kept just moist, and encouraged to make as much growth as possible. The pans should be placed in the cold frame fairly near the glass, and here they may remain undisturbed till the spring, when each plant should be potted off and given a separate existence. Some of the seeds remain dormant until the spring,

so it is not expedient to discard the seed-pans after the first or even the second batch of seedlings has been removed.

Auriculas in the Rock Garden and Border.—In September, 1914, I planted a nice lot of Auriculas in the rock garden and flower border, and in the spring they produced a charming display. The varieties employed were the vigorous Argus, Thetis, Duke of York, Firefly and the beautiful yellow Queen Alexandra. The latter is a delightful kind and should be largely grown outdoors, while it is also very fine as a pot plant. For outside work the best effect is produced by planting them in batches of one kind, and for preference where

A ROUGH STONE WALL PLANTED WITH ROCK ROSE, CERASTIUM, DIANTHUS AND VALERIAN.

it is slightly shaded from the midday sun. An old lady near my residence grows quite a lot of plants in boxes, and the display last spring was very good. They stand on the top of a wall some 4 feet in height, and receive a lot of sunshine; but it is the only position the lady has got for her favourites. T. W. B.

CAMPANULA PROFUSION.

NOTICE that Mr. E. C. Howell, Cheltenham, issue October 16, page 506, brackets this pretty hybrid with *C. haylodgensis*, and in doing so falls into a common error, the true *Profusion* being very distinct. *C. haylodgensis* was raised many years ago at Hay Lodge, Edinburgh. Its presumed parents are *C. carpatica* and *C. pusilla*. *C. Profusion* was raised by myself about a score of years ago,

open. There is no doubt about the seed parent—that was a white-flowered *C. pyramidalis*, though it apparently played but little part so far as external evidence goes. There are in commerce as already indicated, two plants named *C. Profusion*, the one practically a self-coloured blue flower, the other a sky blue, mauve-shaded variety. It was the self-coloured variety to which the award of merit was made. The presence of the two plants under one name is due either to two seedlings having been pricked off together or to a late vegetating seed. A few days after exhibiting the plant I attempted a further cross, and subsequently sold the stock to the late Mr. Selfe Leonard, conditionally that he should await delivery till the seed ripened. The attempted cross was, however, a failure, no seed being produced. In the meantime flowers of the mauve-shaded variety appeared, and though I tried to eliminate the plant, some roots must have survived and, being presently propagated, got into commerce. The

THE TRAVELLER'S JOY AS A WAYSIDE PLANT.

I KNOW of no plant that is so well named as the Traveller's Joy. At the present time many a hedgerow along our country roads is made to look more cheerful owing to its presence. It seems to prefer a chalky soil, for it is on hillsides and downs overlying chalk that this native wilding is seen at its best. More often than not it is observed clambering over a neglected fence or smothering the surrounding shrubby vegetation, and although it is, as a rule, too vigorous as a garden plant, it is, nevertheless, an admirable subject for the wild garden. In the accompanying illustration it is shown growing over Juniper bushes on a chalky hillside in Surrey, by the side of the old Pilgrim's Way. In the summer-time it is cherished by virtue of its sweet almond-scented flowers;

but at this time of year it is even more to be admired, as it garlands trees and hedgerows, producing masses of its smoky grey, feathery seed-vessels that have earned for it the colloquial name of Old Man's Beard. It is, however, by the name of Traveller's Joy that it is most generally known, and it would be interesting to make sure of the origin of this popular name. Can it be for the reason that this wilding is usually associated with some place of habitation, often clambering over farm buildings and fences, and so frequently marking the approach to a country village? It is so often seen on the outskirts of villages, and I have noticed the same peculiarity in the North of France, where this plant was to the writer a real joy last winter, as it invariably marked the approach to an *estaminet*, a welcome place after long marches across open country. It is well known that man has—although, perhaps, unconsciously—influenced the distribution of many wild flowers. Some, like Corncockle and Cornflower, for instance, grow on arable land, some in ditches, some on the scene of old encampments, and others by the roadside;

and if in olden times *Clematis Vitalba* occurred on the outskirts of villages and hamlets—and there is every reason to support this view—then would the charming name, Traveller's Joy, be full of meaning to the wanderer. C. Q.

TRAVELLER'S JOY ON THE PILGRIM'S WAY, SURREY.

and received an award of merit from the Royal Horticultural Society in August, 1896. As there has been some confusion about this plant owing to two forms getting into circulation under the name, its history, which I gave three years ago to correct an error of Mr. Farrer's, might be of interest. I had been endeavouring for several years to obtain crosses between *C. isophylla* and *C. carpatica* varieties as pollen parents, and *C. pyramidalis* variety as the seed-bearer. I believe I persisted for five successive years before getting a fertile seed. Unfortunately, in the year of securing seed, the tags marking the parentage became detached, and I therefore had to make a guess as to the pollen parent. From the position of the capsule I formed the opinion that *C. carpatica* was the male parent; but when the hybrid developed I came to the conclusion that it was *C. isophylla*. This is made more obvious by the foliage when the plant is grown under glass, and is less apparent when the plant is grown in the

sky blue, mauve-shaded variety is, I believe, the more plentiful; possibly, too, the most charming. Both, however, are good and free, and valuable for their late flowering; and both have the characteristic trailing habit of *C. isophylla*, though it is more highly developed, probably, in the self-coloured plant, which is *C. Profusion* proper. The paler form might for convenience be labelled *C. Profusion* No. 2. Few late-flowering members of the race are more worthy. The nearest approach to my pale blue form in flower that I have seen is known as *C. Tymonsii*, but its habit of growth is distinct. E. H. JENKINS.

FORTHCOMING EVENTS.

December 7.—Royal Horticultural Society's Exhibition of Flowers and Fruit, 1 p.m. to 5 p.m. Vincent Square, Westminster.

December 8.—Perpetual-Flowering Carnation Show, 1 p.m. to 5 p.m. Royal Horticultural Hall, Vincent Square, Westminster.

AN EVERGREEN BARBERRY.

AMONG the numerous species of *Berberis* introduced from China by Mr. E. H. Wilson, *B. sargentiana* promises to be one of the most useful. In appearance the shrub resembles the Indian *B. Hookeri*, or *wallichianum* as it is erroneously named in gardens. Sargent's Barberry, however, is hardier and much more suitable for planting extensively in the pleasure grounds and shrubby borders. It grows into sturdy, thick bushes 4 feet to 5 feet or more in height, with effective, dark green spiny leaves. The flowers are yellow, followed in autumn by purple black fruits.

OUR NATIVE TREES AND THEIR CONGENERS.—I.

By W. BOTTING HEMSLEY, LL.D., F.R.S., V.M.H.

AN article by the writer of these lines on "The Oak Trees of the World," which appeared in the issue of THE GARDEN for July 17, page 351, is considered of sufficient interest to justify the publication of a series of short papers on the general distribution of the arboreous genera represented in the woods and forests of the United Kingdom. The series will

The Evergreen Element.—Unlike the forests of wide areas in other parts of the temperate regions of the Northern Hemisphere, evergreen trees, except where planted, constitute a relatively small and unimportant part of our forests, but as gymnosperms (Coniferae, Cycadaceae and allies) are of earlier origin, according to geological evidence, than deciduous types, this element may be considered first. According to the most

at least half a dozen species among the numerous remarkable forms, both wild and of garden origin. *Taxus fastigiata*, the Irish Yew, is one of the most familiar and striking of cultivated Yews. The Yew is of geological antiquity in the Northern Hemisphere, but apparently not represented in the Southern Hemisphere, either in recent or fossil vegetation.

The Scotch Fir (*Pinus sylvestris*).—From fossil remains it is evident that the Scotch Fir was formerly wild in many parts of England. It is still widely spread in the mountains of South Europe and the plains of North Europe and Central Asia. The genus *Pinus* comprises about seventy-

YEW HEDGES AND HERBACEOUS BORDERS.

include some trees whose existence in these islands is possibly, or probably, due to human agency, but controversial points will not be discussed in this connection. It is a known fact that more than a quarter of the species of flowering plants now growing wild in New Zealand are aliens, and some of these are rapidly replacing native species and changing the face of the vegetation in certain localities. But of this more anon.

The arboreous elements of our woods and forests are of two kinds, namely, evergreen and deciduous.

generally accepted classification at the present time, the Coniferae are divided into two families, Taxaceae and Pinaceae, both of which families are represented in our forests by one species each.

The Yew (*Taxus baccata*).—*Taxus baccata* is a comprehensive and variable species in the eyes of many eminent botanists, and is spread all around the Northern Hemisphere, ranging latitudinally from Japan, the Himalayas, Taurus, Atlas and the mountains of Mexico, almost to the Arctic Circle, in places. Other botanists recognise

five species, encircling the Northern Hemisphere and extending southward to the Philippine Islands, the Mediterranean region, including the Canary Islands, the West Indies and Nicaragua, Central America. No species is known to exist in the Southern Hemisphere, but there is a record of a fossil Pine forest in Eastern Australia. It is, however, uncertain to the writer what is there meant by *Pinus*, because at the present time the species of the large and characteristic Australian genus *Callitris* are called Pines. The greatest concentration of the species is in North

America, on the west coast, and the mountains of Mexico, where they range from the sea-coast to altitudes of 10,000 feet to 14,000 feet.

The Box (*Buxus sempervirens*).—Although the Box, as usually seen, both wild and in cultivation, is of shrubby habit, under the most favourable conditions it assumes tree-like proportions, attaining a height of 30 feet to 50 feet. *B. sempervirens* covers a wide geographical area, extending from the Canaries and the South of England through Europe and North Africa to China and Japan. The genus *Buxus* comprises about a score of species almost or quite restricted to the Northern Hemisphere in Europe, Asia, Tropical

Norway to the Mediterranean, the Himalayas and China. Although most commonly only a large shrub, in favourable conditions it becomes a tree 30 feet to 50 feet high, and exceptionally as much as 75 feet high. Although so numerous in species and so widely spread, *Ilex* is exceedingly rare throughout Africa; only one species is recorded from Australia, and the genus is unrepresented in New Zealand. The greatest concentration of species is in South America, chiefly in the sub-tropical region.

The Strawberry Tree (*Arbutus Unedo*).—The evergreen Strawberry Tree, a member of the Ericaceæ, is limited, in a wild state, within the United Kingdom, to the South-West of Ireland, where it is probably indigenous, and it is recorded as abundant in some localities. Though commonly cultivated in the South of England, it does not seem to have established itself in a wild state. Its range is Western and Southern Europe, eastward to Asia Minor. The genus *Arbutus* numbers about ten or a dozen species, inhabiting the Mediterranean region, including the Canaries, and North America, from Oregon to Guatemala. Other genera now nearly confined to the Mediterranean region and America are *Helianthemum*, *Lupinus*, *Heberdenia*, *Platanus* and *Corema*.

PEACH TREES AND VINES.

I AM a firm believer in early root-pruning, that is, at this season, rather than in February. If Peaches are making extra strong growth and are not fruitful, lift, root-prune slightly, and

replant. Use a peck of slaked lime and two pecks of old mortar rubble to each tree, mixing these ingredients with the soil and making it very firm round the roots again. Next to the bare roots put some gritty soil not containing lime. Give water freely, lay on a surface mulch, and syringe the branches three times each week for two weeks. If the trees are in houses, keep the ventilators open night and day.

Renovating Vines is often found to be necessary in the case of old Vines. Some are so useless that it is better to root them out, remove the old soil, and plant young Vines in fresh soil. But others are greatly benefited by lifting the roots from a cold subsoil and relaying them near the

surface in new loam. This work should be done when the leaves are falling freely from the Vines, also in November. Put mats on the glass over the Vines; keep the leaves and rods moist by syringing every morning; have the new soil ready to replace the old; lift the roots carefully, wrap them in wet sacks or mats while the new soil is being put in; then spread them out evenly and cover them 4 inches deep. Here, again, a surface mulch is beneficial, also a firm rooting medium. Prune the Vines as soon as all the leaves have dropped off. G. G.

SOME RELIABLE PEARS.

UNLIKE the Apple, the majority of Pears are not remarkable for their keeping qualities. The Pears that are grown should be of the finest quality; that is, they should be of good flavour, reliable croppers and disease resisting.

Autumn Nelis is a really fine Pear, in season during the early part of October. In flavour it is somewhat similar to the well-known Winter Nelis, but it has a better constitution and produces larger fruits than that variety. It is best on the Quince stock, and succeeds admirably as a cordon on a south wall.

Louise Bonne of Jersey is too well known to need description, in season a few days later than the last named. It is a good old reliable variety, is first-rate as a wall tree trained in any form, or it will make a good standard. It is a most reliable cropper, and in all ways a good dessert Pear. It is best grafted on the Quince stock.

Marguerite Marillat.—Although not so good as Doyenné du Comice in flavour, this variety usually crops well even on a poor soil and in a bad Pear season. It is a large, handsome fruit of sugary, aromatic flavour and beautifully coloured. It is in season during September and early October.

Fondante d'Automne is a good October Pear when grown as a cordon on a south or west wall. It is a most reliable cropper, and will produce large fruit if well cultivated. Quince stock for wall trees.

Doyenne du Comice is undoubtedly the finest dessert Pear. It is a free bearer and healthy; and will succeed trained in any form or as a bush or pyramid, and will bear abundantly in almost any position. The fruit is of good size and attractive appearance, especially if wrapped in tissue paper and placed in heat for two or three days previous to consumption. This variety bears freely in an early stage when grown on the Quince stock; but if on the Pear stock, some years will elapse before a good crop is realised. Ripens in November.

Glou Morceau is a fine December Pear for a warm wall, but is rather subject to disease on cold soil. The tree should be sprayed regularly to prevent fungus, or the fruit may be affected by this disease. A large, handsome Pear of good flavour. Quince stock.

Josephine de Malines is a fine Christmas Pear, perhaps the very best for this season. It succeeds on either the Quince or Pear stock, and bears freely as a cordon, a horizontal-trained tree, or as a bush, but it does not make a shapely specimen. Hard pruning should not be resorted to with this variety, but careful root-pruning is essential.

PEAR MARGUERITE MARILLAT AS A CORDON ON A WEST WALL.

Africa and the West Indies. Absence of the genus from Continental America is noteworthy. *B. balearica* is a handsome, small tree, deserving of wider cultivation in the western milder parts of the kingdom.

The Holly (*Ilex Aquifolium*).—The common Holly, the pride and ornament of our woods and gardens, belongs to a genus of some 300 species of almost world-wide distribution in temperate and warm countries, constituting a family in itself—the Aquifoliaceæ. It is the only native evergreen tree of wide dispersal in the United Kingdom, affording a striking contrast to the arboreal vegetation of Japan, for example. Outside of Britain this species ranges from South

Thompson's is a splendid November Pear, but, unfortunately, is a shy setter, so it should always be planted in close proximity to a free-setting variety in order to become fertilised. It is at home on a south or west wall.

Beurre Hardy and Marie Louise are excellent late October and November Pears, but are so well known that description is needless. The former, grown in any form or position, is especially valuable for its free bearing. The latter prefers a south or west wall, and both succeed on the Quince stock.

RALPH E. ARNOLD.

BOOKS.

The Door in the Wall, or The Story of My Garden*.—This little book is a beautifully illustrated history of the making of a small suburban garden "where four roads meet," somewhere near Manchester. The authoress, Mrs. Duggan, tells us that the design, more or less her own, may fairly claim to have made much out of little, and the excellent plan which accompanies the text more than bears out her statement. We are glad, too, to allude to the fact that the door in the wall "is often left open, especially on Bank Holidays, when many little parties enjoy a personally conducted tour round our corner plot." The objects of the book are two-fold—one, to encourage the women of this country to personally design and cultivate their own gardens; and the second and even more important object is the announcement "that the net proceeds resulting from the sale of this book are to be devoted to founding 'The Manchester Regiment

Beds in Roehampton House, Queen Mary's Convalescent Auxiliary Hospital for Sailors and Soldiers who have lost their limbs in the war.'" The Dean of Manchester, in an excellent preface to this little book, states: "Mrs. Duggan has conceived the generous idea of raising money enough to support a bed for some crippled soldier of the Manchester Regiment in Roehampton House. It is a pleasure to give her any help. She is an expert gardener . . . and no act of sympathy or reverence can, I think, be too great for the gallant regiment which has crowned its honour in the Crimea, in Afghanistan, in Egypt, in South Africa, and elsewhere, by its noble service in the present dreadful war." To this we need only add that the authoress was for many

years the hon. secretary of the Bowdon Horticultural Club, under whose auspices the gardens in the neighbourhood enormously improved. It is a little book with a great purpose.

Rock Gardens and Alpine Plants*.—Anyone about to construct a rock garden will find this work to be a veritable mine of information on the subject. It will be no less valuable to those who already possess such a garden and contemplate alterations therein, while the list of plants suitable for different positions is large and comprehensive. Although the work is edited by Mr. T. W. Sanders, the "Rock Garden" is dealt with by Mr. E. H. Jenkins, and the "Moraine" by Mr. S. Arnott. Each subject is, as can be readily understood when the experience of the contributors is borne in mind, treated in a thoroughly practical manner. The scope of the work is shown by taking Part I., "Construction

neasters, might well have been included. Some of the illustrations are very good, but the coloured plates might have been omitted without lessening the value of the book.

FLORENCE FENNEL.

This vegetable was shown at the Royal Horticultural Society's meeting on November 9 by Mr. Dawkins in his interesting exhibit of vegetables. Although the plants were rather small, they were a reminder that they can be easily grown in this country. In Florence, where it is known as Finocchio, or Fenouil, it is brought to the markets in cartloads, and is a great favourite with working people there. It is grown in other parts of Italy as well, and also to a smaller extent in France. It slightly resembles Celery in shape and habit of growth, as the base swells to a large size when

THE NANKEEN LILY (*LILIUM TESTACEUM*).

An illustration from "The Door in the Wall."

of Rockeries" and its attendant eight chapters. They deal with Selection of Site, Aspect and Position, Materials for Rockeries, Principles of Rockery Building, Formation of Rockeries, Miniature Rock Gardens, The Simple Rockery, and Rock-studded Banks. It will thus be seen that every phase of the rock garden is exhaustively dealt with. The almost total absence of errors shows that the proofs have been carefully read, though, in the index, the word *Fritillaria* has got out of its proper place. Again, in the selection of shrubs for rock gardens, a few of the newer Chinese importations, particularly the *Berberis* and *Coto-*

well grown. I find it succeeds best when sown in shallow drills about 18 inches apart and the plants thinned to a foot in the rows. It prefers rich, well-manured and deeply-worked soil, and when growing requires plenty of water. In about six weeks from sowing the seed the plants are ready for earthing up, and the side growths should be removed. The soil should be drawn up in the same way as for Celery. When the plants are sufficiently blanched, they can be used either boiled and served with sauce, or eaten raw as a salad. Finocchio has a rather aromatic smell, and a sweet taste resembling aniseed. It can be lifted and stored in moist sand when necessary as if left too long in the ground it will run to seed.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Winter Cucumbers.—In order to keep the plants in a healthy, fruit-bearing condition, it is essential that they are kept free from red spider. Syringing once a week with a solution of soft soap and sulphur will keep the foliage free from this pest. Stop and tie the shoots regularly, and give them plenty of room. The roots will not be in need of so much water as formerly; a good watering once or twice a week will be ample. An occasional sprinkling of artificial manure over the rooting area is all that is required in the way of stimulants. Keep an equable temperature of about 65°. Should very severe frosts occur, cover the glass with mats or tiffany.

Early Pot Vines.—When the buds show signs of bursting into growth, the temperature may be raised about 5°, increasing it as growth proceeds. Tie up the rods to their permanent position on the trellis as soon as the buds are breaking freely. Lose no time in removing the surplus shoots as soon as it can be determined which are carrying the best bunches. The roots must be well soaked with water when they are in need of it. It is a good practice to give two waterings to ensure the ball of roots being soaked right through. Discontinue syringing when all the buds have broken into growth, but promote a moist atmosphere by damping the walls and paths as often as necessary. If the temperature of the hot-bed declines too low, some fresh materials must be added to it.

Plants Under Glass.

Malmaison Carnations.—These must be kept cool; only in the case of very severe frost will artificial heat be necessary. If not already done, the young plants may now be potted into 6-inch pots. Fibrous loam, leaf-soil, brick rubble and coarse sand form a suitable compost. When potted, the plants must be very carefully watered till the roots have taken hold of the new soil.

Lily of the Valley.—Retarded crowns must be used to keep up a supply of flowers till the turn of the year. Clumps may then be dug up from a well-established bed outdoors and placed on a hot-bed in a heated pit. Cover the roots with soil, and water them with tepid water. Light must be excluded from the pit till the spikes are 4 inches or 5 inches high; the plants may then be gradually exposed to the light.

Allamandas.—These may now be pruned, and if growing in pots they may be placed in a cool house for the winter and kept on the dry side. Cut the shoots back to two or three eyes. Specimens which are growing in a border may be pruned similarly, and kept as dry as possible at the roots.

The Flower Garden.

Border Carnations.—After a spell of frost it will be necessary to examine the plants in the border, and any which have become loose must have the soil carefully pressed around them. The plants must be protected from birds and mice, which often do a deal of mischief. When the ground is dry enough, run the hoe between the plants. Plants in frames must have abundance of air, leaving the lights off altogether whenever the weather is favourable.

Montbretias.—The corms of these useful flowering plants should be lifted annually and stored in boxes in a cold frame. I have tried lifting them every two years, but find they produce better flowers when lifted every year. The ground should be deeply dug and well manured before replanting them in the spring.

Protecting Plants Out of Doors.—No time must now be lost in placing protecting materials over plants which are not sufficiently hardy to stand severe frost. Evergreen boughs or Bracken will form suitable protection for many plants; a few ashes placed round the collars of others will suffice.

Plants in Cold Frames.—These must be carefully examined occasionally and all dead foliage and rubbish removed, or many will be lost through damping. Much care will be needed in ventilating the frames. When the weather is very mild the lights may be lifted off. All the light

possible must be admitted to the plants, and it may be necessary to clean the glass should it become obscured by dirt or fogs.

The Hardy Fruit Garden.

Figs.—As soon as severe weather sets in, Fig trees outdoors must be protected. Release the branches from the walls, tie them in bundles, and cover them with straw or Bracken. Trees which require root pruning may be dealt with at any time from now till the spring when the weather is open. To be successful with Figs, they must be grown in a shallow, restricted border with plenty of drainage.

Outdoor Vines.—The pruning of outdoor Vines may be done now; cut back the lateral growths to two or three buds. If the rods have been trained too closely together, some of them should be cut out; they should be not less than 3 feet apart. After pruning, a portion of the surface soil may be removed and replaced with new compost, which may consist of rich loam, wood-ashes, brick rubble and crushed bones.

The Kitchen Garden.

Cabbage.—Any blanks in the beds must be made good; afterwards run the hoe between the plants and draw a little soil around the stems. Dust the plants with lime as a precaution against slugs.

Carrots.—A sowing of Scarlet Horn Carrot may be made at any time now. A hot-bed of moderate warmth is necessary on which to place the soil. A layer of good soil, about 9 inches deep, should be placed on the hot-bed and made moderately firm. Sow the seeds broadcast and keep the frame close till the young plants are through the soil. Ventilation must then be afforded, more or less according to outside conditions.

E. HARRISS.

(Head-gardener to Lady Wantage.)
Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Plants Under Glass.

Chrysanthemums.—The main batch of cuttings of all varieties should now be potted as the shoots become large enough for taking. They are best when kept cool from the commencement, so that where a pit or house can be devoted entirely to them, very little pipe-heat, except during frost, will be required. Air must be admitted with caution, or flagging will take place. If the cuttings are to be rooted in frames or hand-lights, the covers should be left off for some time each morning to allow all moisture to escape from off the glass.

Gloriosas which have now thoroughly ripened their growths can be cut over, and the pots containing the tubers laid on their sides underneath the stage of a warm greenhouse.

Tree Carnations.—A start can now be made to propagate these plants. The small growths which appear on the flowering stems root more freely and eventually form better plants than those taken from the base of the plants. Bottom-heat, if used, must be very mild; in fact, it is not imperative, as cuttings root readily if kept in small frames or hand-lights placed on a Carnation-houses stage. Pure sea-sand should be used, or if soil, then it must be very light. A slight shading is necessary for a short period about midday when the sun is bright.

Fruit Under Glass.

Early Peach or Nectarine House.—Where fruit is required during May, a start must be made by closing this house. Very little pipe-heat should be used in the early stages. The trees may be syringed during the mornings of bright days. If the borders were attended to in regard to watering when the leaves were falling, no water should be required for some time to come; but if there is any doubt of the borders being moist, they had better first be watered. A temperature of 50° will be quite high enough during the night, allowing it to advance somewhat during the day.

Succession Houses.—The annual cleaning and general overhauling should be done as early as possible, so that there may be no danger of the buds swelling before it is completed. For the

woodwork and glass use plenty of soft soapy water, and for the trees Gishurst Compound is a reliable dressing. Where disbudding has been done properly, there will not be much need for pruning; but this must be resorted to rather than overcrowd the wood. When there is an abundance of young wood on vigorous trees, it is sometimes possible to remove altogether one or two of the older branches which become bare towards the centre of the tree.

The Hardy Fruit Garden.

Pruning.—Now that the foliage has fallen, pruning can be proceeded with on Apple and other trees growing in the open. Where fruit trees are growing among other subjects and not occupying an orchard by themselves, the system of pruning will greatly depend upon the space available. The common habit of planting fruit trees in vegetable gardens has many drawbacks, and where a separate portion can be devoted entirely to fruit growing, better results are obtained.

The Flower Garden.

Roses.—When new Rose-beds are being made, it is of vital importance to have perfect drainage; especially is this so in low-lying positions situated on either rock or clay beds. Roses thrive in rich soils, so that where new beds or borders are being formed, it should be seen that there is plenty of nourishment for the trees, given in the form of manure, turf and other additions which can be made.

Herbaceous Border.—This should now be cleared entirely of all growths. When possible these should be burnt, the ashes being kept and returned to the soil. All stakes should be put away, in order to prevent confusion and delay when they are again required.

Dahlias.—The tubers which were lifted some time ago are dry and ready to be stored away for the winter. A fairly dry and frost-proof place is necessary, but it is of great importance that it should be cool.

Wild Garden.—Many subjects in this department are not quite hardy, and will require to be protected on the arrival of frost. Tritomas and Gunneras are among the first to suffer during a severe winter. Spruce and Yew branches are splendid for covering, as they are easily removed when mild weather returns. Some plants having a herbaceous habit can be covered with a few inches of ashes, which prove a splendid protection in many cases.

The Kitchen Garden.

Asparagus.—The crowns should now be in good condition for forcing. A mild hot-bed is equally as good as bottom-heat produced by pipes. But, whichever is used, it should be brisk enough to encourage a quick growth, which is necessary to produce tender growths. These should be cut daily as soon as they reach the proper size, and can be kept standing in water until required. Fresh batches should be introduced to heat, not less frequent than every fortnight where a regular supply has to be maintained.

Cucumbers.—This crop during the winter frequently gives trouble owing to various causes, the most common being lack of sufficient heat and light, combined with overcropping. The production of fruits must be restricted, and a little fresh air admitted whenever the conditions outdoors will allow of it.

Chicory.—New batches should be brought into the Mushroom-house as may be required. About a fortnight is usually long enough to blanch the plants ready for use.

Celery.—In view of possible severe frost, which would do damage, some clean straw or Bracken should be got in readiness for covering up the plants during a storm. As this covering is apt to retain an undue amount of moisture if left on, which would eventually spoil the Celery, it is best to uncover the plants on the return of open weather.

Artichokes, Parsnips and Salsify.—A quantity may be lifted and covered with soil in some sheltered quarter where they could be conveniently obtained if required during a continuation of severe frost.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)
Castlemilk Gardens, Lockerbie, N.B.

THE 1915 "DAFFODIL YEAR BOOK."

AS it is possible that the review of the above by the Rev. G. H. Engleheart, which recently appeared in your columns, may influence the character of future Year Books, I should like to make a few remarks upon two points whereon I think that many will differ from the rather *ex cathedra* pronouncements of the reviewer.

The first refers to the illustrations. Some, I know, are of opinion that the "Personal Picture Gallery" creates a less wide interest than floral illustrations which serve to convey to those who are not always able to visit the shows some idea of what the latest best varieties are. But as the remaining available material for the picture gallery must by this time have assumed greatly diminished proportions, and new varieties, on this line, do not come forward in sufficient numbers, the point will settle itself, and need not now be further urged.

We certainly can do without portraits of "old stagers" like Santa Maria, and freaks like Elfin, also without melancholy perspectives of Empress or any other Daffodil; but we do want adequate illustrations of the newer and more important Daffodils which each season brings us.

As to the character of these illustrations I entirely dissent from the views expressed by Mr. Engleheart, who, obviously, is no photographer. Pen and ink outlines, however well executed, would be but poor substitutes for the more exact rendering given by such excellent photographs as we have had in the Year Books.

Colour photographs would undoubtedly be preferable, but expense forbids; but, having regard to the limited circulation of the Year Book, hand colouring might come in, at no very great additional cost. Mr. Engleheart assumes it to be impossible to depict a suggestion of colour differences in a photograph by the use of colour screens, whereas, as a fact, it is not at all inevitable that a flower like Ixion must be shown "just as white all over"—to quote your reviewer—"as Centaur." If Mr. Engleheart studies his "Daffodil Year Books," as I hope he does, attentively, he will have noticed in the 1913 edition an excellent photograph of Narcissus Pedestal, also one of Touchstone, which entirely dispose of his notion on this point. Obviously a suitable colour screen was not, but should have been, used on Ixion, but this does not affect what can be done.

I hope that the editor of the Year Book will not be influenced to discontinue his admirable and useful series of photographic illustrations of the newer best varieties.

The other matter which I should like to notice is that in which Mr. Engleheart condemns as "valueless" Dr. Lower's tabulated lists of crosses. To a novice like myself they prove most useful, both in the negative aspect of warning us off supposed seed parents which will not, or only very rarely, seed, and also, affirmatively, by showing us what crosses will at any rate produce seed, and the general principles of selection of parents which have been productive of the excellent results shown by Dr. Lower at our exhibitions. And what are Mr. Engleheart's objections? Mainly that Dr. Lower calls his crosses "successful." But they

have proved successful within the narrow limit stated by Dr. Lower, in that they have produced seed. That is all he claims. But Mr. Engleheart suggests that it is "absurd" to call a cross "successful" before the seedling has flowered, attacking Dr. Lower's employment of the term on the ground that the cross now called "successful" may, when flowered, prove to be but the result of the "remarkable way" in which "flowers manage to fertilise themselves" despite "the most complete depollination."

I think that even my own limited experience enables me to say that Mr. Engleheart greatly magnifies the importance and extent of the influence which he suggests as practically nullifying the value of Dr. Lower's conclusions. I am inclined to believe that Messrs. Cartwright and Goodwin, in their "Latest Hobby," more accurately state the true position when they say, on page 56, "no doubt certain flowers are often self fertilised, but in most cases we have found that if the operation is properly carried out, and seed is produced, the result generally shows the desired cross to have taken place."

In my own case I have had, on an average, eighty bulbs of Mme. de Graaff planted in rows in my special Daffodil borders. By far the larger number have been each year "left to the insects." As to the remainder, taking the years 1910 to 1915 inclusive, cross-fertilisation has given me 115 crosses producing seed, while during the same six years, and under exactly similar conditions, the other rows, the large majority "left to the insects," gave but fifteen seed-pods, either self or insect pollinated, thus fairly establishing a ratio showing that the proportion of Dr. Lower's 172 crosses possibly due to self or insect pollination, and not to the intended cross, is practically very small, certainly totally insufficient to justify your reviewer's wholesale condemnation of the lists as "valueless," or the use of the word "absurd" in connection with Dr. Lower's work.

I trust that, *pace* the Rev. G. H. Engleheart, the editor of the Year Books will continue to supply information of the character in question, so very welcome to—A NOVICE.

ANSWERS TO CORRESPONDENTS.

THE GREENHOUSE.

STREPTOSOLEN JAMESONII NOT FLOWERING (E. P. D.).—It is quite impossible for us to state definitely the reason of your plant of *Streptosolen Jamesonii* not flowering. You give us no idea of the way in which it is treated, whether grown in a pot or planted out in the greenhouse. As it has flowered so well for the last five years, and you have doubtless continued the same treatment, it would not appear that this is at fault. A possible cause is that the soil is exhausted, and the plant has therefore not strength to flower; while it may be attacked by red spider, to which it is sometimes liable.

TREES AND SHRUBS.

ABNORMAL FRUIT TO NAME (A. J. B.).—The spray enclosed with fruits is *Cydonia (Pyrus) japonica*. When the flowers survive frost, the bushes fruit freely; but the specimen sent is quite abnormal, due to flowering out of season, apparently in late summer.

A DIFFICULT SHRUB TO GROW: CUPRESSUS MACROCARPA (Macrocampa).—*Cupressus macrocarpa* is one of the most difficult of all trees to establish successfully, but when planted in suitable situations, i.e., the milder counties and preferably within a few miles of the sea, it is one of the most satisfactory of shelter trees after it has once become established. The best results are usually secured by planting quite small plants 9 inches to 12 inches high in spring. Those larger than that should be planted from pots, and a stake should be placed to each one to keep it from being blown about, for the branch growth is usually out of all proportion to the

root system, and wind pressure causes the top to sway about and loosen the roots, thereby giving them no chance to form new root fibres. Even small plants must be planted quite firmly to enable them to become established. In the most satisfactory plantations a fair number of losses must be expected.

TO PROPAGATE DOUBLE-FLOWED FURZE (V. C.).—The best way to increase double-flowered Furze is to take short cuttings of the current season's wood, about 4 inches long, in August and insert them firmly in sandy soil in a close but quite cold frame. Make the cuttings with a slight heel of older wood, such as is obtained by detaching them at the junction with the older wood. Make a bed of sandy loam and cover it with silver sand; then, after removing the spines and leaves from the lower halves of the cuttings, insert the cuttings to about a third of their depth. Water them as soon as inserted, and shade them from bright sunlight. Give sufficient water afterwards to prevent the soil from becoming dry, and slightly damp the cuttings after a hot day. Keep them close until new shoots begin to grow, when air may be admitted. They ought to be well rooted by the following April, when they must be lifted carefully and potted singly in 3-inch pots. Replace in the frame and keep close for a few days. When the pots are well filled with roots, place the plants in permanent quarters.

ROSE GARDEN.

RUST ON ROSE LEAVES (Subscriber).—Your Roses are badly attacked by rust, and it would be well to gather and burn the leaves as they fall, as far as this can be done, for the fungus rests on the fallen leaves through the winter to attack the shoots in spring. The disease causes premature leaf fall, and it is therefore very desirable to check it as far as possible. The spraying of the bushes with a rose red solution of potassium permanganate is a means of checking the spread of the trouble.

FRUIT GARDEN.

GRAPES NOT COLOURING (G. H. L.).—Apply sulphate of iron in the form of powder at the rate of 3oz. per square yard, or when topdressing the Vine border mix a 6-inch potful of it with each barrow-load of soil. Be sure, in the first instance, that the soil is deficient in iron, as overcropping is a frequent cause of poor colour.

BLACK AND RED CURRANT CUTTINGS STRUCK LAST AUTUMN (K. F.).—Better results will follow by transplanting the young trees into rows 2 feet apart, allowing the same distance between the trees in the rows, and then planting in their permanent quarters next autumn.

THE CHERRY AS A GRAFTING STOCK (E. Blinco).—Your clean young Cherry trees may be used for grafting any other variety of Cherry on, but no other kind of fruit. How would the Morello Cherry suit you? This variety succeeds very well in bush form, and the birds are not so partial to it. In any case, the bushes could be netted.

APPLE HUDSON'S SEEDLING (J. D. W.).—We have such a rich and excellent collection of late cooking Apples that the seedling sent has no chance of being included among them. Therefore, from this point of view, its further propagation would be of no advantage. But as a local variety, well suited to the neighbourhood in which it appears to do so well, the case may be quite different.

BRANCHES OF GOOSEBERRY FOR INSPECTION (Puzzled).—Your Gooseberries have been badly attacked by aphids during the past year. It would be well to prune out all the malformed shoots and to spray the bushes before the beginning of February with caustic soda, 1lb. to 12 gallons of water. As soon as aphides make their appearance in spring, and while they are still quite small, spray the bushes with Quassia and soft soap, or with a nicotine preparation.

WALNUTS WITH IMPERFECT SHELLS (W. Norwood).—The imperfection in the shell of the Walnut may arise from various causes. 1. It may be a normally very thin-shelled variety—seedling Walnuts differ markedly in this character. 2. Rooks may have pecked the fruits as they were developing, as they are very fond of doing. 3. The young fruits may have been slightly injured by frost, which checked the growth of parts of their outer walls. 4. Possibly there is a deficiency of lime in the soil.

APPLE TREES NEAR THE SEA IN SANDY SOIL (M. P.).—Without protection from high winds and storms and a liberal admixture of loam and marly soil to the sand, we think the prospect of success would be hopeless. The following would be the most likely to succeed: Beauty of Bath, dessert, ripe in August; Devonshire Quarrenden, dessert, September; King of the Pippins, dessert, October; Allington Pippin, dessert, November; and Gascoyne's Scarlet, dessert, Christmas. Grow in the form of low bushes on the Crab stock.

INJURY TO APPLE (B. F. J.).—Your Apple is suffering from two attacks. First, it was attacked by aphides early in the season and their punctures have disfigured it. The remedy for this is prompt spraying as soon as the pests appear in spring. Secondly, the fruit is attacked by the trouble known as bitter-pit. This is due to some physiological cause connected with irregularities in the water supply. The only recommendation that can be made with regard to it is to endeavour to regulate the water supply as much as possible by watering when necessary, and especially by keeping the surface soil well stirred during the summer. The brown spots in the flesh are due to this trouble.

SALE OF WALNUTS (H. B.).—Whether it is more profitable to sell Walnuts green for pickling, or when ripe and ready for dessert, we have no precise information on this point. Against the former, we think that the labour of gathering by hand would tell heavily. We are inclined to favour marketing when ripe for dessert. The demand for Nuts generally, we understand, is good this year. English Walnuts are selling at Covent Garden Market at about 4d. per pound, and French at from 8s. to 10s. 6d. per bag.

PEARS CRACKING (G. S.).—The Pears are attacked by the fungus *Fusicladium pirinum*, which causes the disease known as scab. It would be well to prune out all the diseased portion of the tree, which may be recognised by the cracks on the young shoots and spurs, and then, just before the flowers open and again after the petals have fallen, to spray the trees with Bordeaux mixture.

MISCELLANEOUS.

BIRDS AND PYRACANTHAS (D. G.).—The only way of preserving the fruits is to net the bushes.

LAWN GRASS (A. S.).—The grass sent for identification is the Sheep's Fescue (*Festuca ovina* var.); this particular variety is *tenuifolia*. It is one of the best of all lawn grasses, and seed could be obtained from any of the leading seedsmen, such as Messrs. Sutton of Reading, Messrs. Carter of Raynes Park, Messrs. Dickson of Chester, &c.

NAMES OF FRUIT.—Tielie.—1, Blenheim Orange; 2, Kedleston Pippin; 3, Northern Greening; 8, Golden Spire. All the others were too decayed to name.
C. B. R.—1, Court Pendu Plat; 2, Miller's Seedling.

SOCIETIES.

WARGRAVE AND DISTRICT GARDENERS' ASSOCIATION.

ON Wednesday evening, November 17, Mr. Robert Doe of Parkwood Gardens lectured on "Vine Culture." He is a most successful Grape-grower, and his remarks were listened to with great attention as he gave the members the benefit of his experience. First he briefly touched on the history of the Vine and its cultivation in England, mentioning a few of the most remarkable ones to be found in this country. He then took the following points and referred to each in detail: The kind of house best suited for Vine-growing, heating the same, propagation by means of layers, eyes, seedlings and cuttings; the formation of the Vine border, soil, planting out, manuring, forcing, distributing the pollen, thinning, stoning and colouring. A good discussion followed, and Mr. Doe was heartily thanked for his lecture. Mr. T. Bachelor of Bolney Court Gardens exhibited a fine collection of Perpetual-flowering Carnations, and was awarded a cultural certificate by the judges.

Croydon Horticultural Society.—At the annual general meeting of this society, held on Tuesday, November 22, at the Town Hall, Croydon, His Worship the Mayor of Croydon in the chair, it was unanimously agreed to hold the summer flower show on Wednesday, June 21, 1916, the profits to be given to a war charity to be agreed upon at a later date. As a result of this year's show, a cheque for £102 4s. was handed to His Worship the Mayor of Croydon in aid of the war relief funds.

United Horticultural Benefit and Provident Society.—The monthly meeting of this society was held at the Royal Horticultural Society's Hall on Monday, November 8, Mr. Charles Curtis presiding. Before the commencement of the business a vote of sympathy was passed to Mr. James Hudson, V.M.H. (senior trustee) on the death of his beloved wife, which was carried in silence, all the members standing. Three new members were elected. One member was allowed to withdraw £48 12s. 3d. from his deposit account, still leaving £10 to his credit in the society's books, and one lapsed member withdrew £42 7s. 7d. Two members were also assisted from the Convalescent Fund. The sick pay for the month on the ordinary side amounted to £69 6s. 3d., on the State Section to £19 7s. 8d., and maternity claims amounted to £9.

The War Office notifies that from now onward all papers posted to any neutral European country will be stopped, except those sent by publishers and newsgatherers who have obtained special permission from the War Office. Such permission has been granted to THE GARDEN, and subscribers who send to friends in Denmark, Holland, Norway, Sweden, Switzerland, Spain, Portugal, Greece, and Roumania should order copies to be despatched by the Publisher from 20, Tavistock Street, Covent Garden, W.C.

*** The Yearly Subscription to THE GARDEN is: Inland, 6s. 6d.; Foreign, 8s. 9d.

LETHORION

IMPROVED METAL

VAPOUR
CONE

FUMIGATOR

INTRODUCED 1885.

Registered Trade Mark, 62,957

THE marvellous effect of this simple and cheap method of Fumigating Greenhouses is fully borne out by the enormous increase of sales year by year.

Only a match required for the proper starting of the cone to secure startling results.

Cone No. 1, for Frames and "Lean-to's" up to 1,000 cubic feet. Price 6d. each.

Cone No. 2, for small Greenhouses up to 1,500 cubic feet. Price 8d. each.

Cone No. 3, for general use in large Greenhouses, 2,000 to 2,500 cubic feet. Price 1/- each.

Full Directions accompany each Cone.

Ask for list of Testimonials, of which some hundreds have been received from the leading Gardeners in the Kingdom.

To be had from all Dealers in Horticultural Sundries throughout the Kingdom.

Manufactured by **CORRY & CO., Ltd.**

At their Bonded Chemical Works, Shad Thames, S.E.

Over 200 pages and 60 full-page illustrations.

Published at the Offices of "COUNTRY LIFE," LTD.,
20, Tavistock Street, Covent Garden, London, W.C.

NOW READY.

"The Door in the Wall" OR The Story of My Garden.

With a Preface by the RT. REV. BISHOP WELDON, Dean of Manchester.

Large 8vo, with double-page plan and excellent illustrations,
1/6 net, by post 4d. extra.

Mrs. DUGGAN is well-known as an expert gardener, and the Story of her Garden is full of practical suggestions and valuable hints. But the chief aim of this charmingly illustrated little book is to raise money to support a bed for crippled soldiers of the Manchester Regiment in Roehampton House. The book is a woman's token of undying admiration and respect for all those brave men, who, by their devotion and self-sacrifice in answering the call of King and Country, have added so much to the glory of the Regiment. It is a direct appeal to all who cannot go to the war, to do something, however small, for those maimed for life in doing so much for you!

Orders for copies of the book should be sent direct to the author,
MRS. DUGGAN, "CLEVEDON," ST. JOHN'S ROAD, ALTRINGHAM.

SITUATIONS VACANT.

Our charge for advertisements under the above heading is 9d. per line, consisting of eight words to the line. Free day Friday.

WANTED by the Scottish Co-operative Wholesale Society, Limited, 95, Morrison Street, Glasgow a man to assist in superintending and developing the Society's Agricultural Interests in West Africa; must be of good character, and knowledge and experience of Tropical Culture essential. Salary, £250 per annum.—Applications to SECRETARY, S.C.W.S., at above address, with testimonials (copies only), to be received not later than Monday, 29th inst.

CLEARANCE SALE.

Owing to our works being given over to Government orders and more space being required for additional machinery, we are prepared to offer our stock of

THE GARDEN.

No. 2299.—VOL. LXXIX.

DECEMBER 11, 1915.

NOTES OF THE WEEK.

Gardens for Little Londoners.—The London Children's Gardens and Recreation Fund brings health and happiness to little Londoners. Eight gardens have been open all the summer, and by the generosity of an anonymous donor another one will be added next year. The gardens are all in the poorest districts of London. Each child has his or her own plot of ground in which vegetables and flowers make a wonderfully fine show, and great is the delight of the children when the Carrots and Lettuces are large enough to be taken home. Any subscriptions on behalf of this worthy fund will be received by the hon. secretary, Mrs. Lyons, 3, Durham Place, Chelsea, who will gladly give any further information.

Farmers' Red Cross Sale.—The following account, taken from the *Bedfordshire Standard* of December 3, records a splendid price for a bouquet sold in aid of the British Red Cross Society: "The company had now assumed immense proportions, and a ringing cheer went up as Mr. J. A. Whitchurch handed Lady Amptill a magnificent bouquet of red and white Carnations, supplied by Messrs. Laxton. Bidding was brisk, until Mr. J. Arnold Whitchurch became the purchaser at £12 12s., and handed the bouquet back to her Ladyship. It was then split up into button-holes, and Mr. Walter Peacock was soon selling at a lively pace; one button-hole, sold three times, must have realised £5, and the average price was 30s., the bouquet realising the handsome total of £62 11s."

The Hardy Yellow Jasmine.—Of all the flowers that brave the wintry weather, none can excel the yellow Jasmine (*Jasminum nudiflorum*) for cheerful effect. Its leafless twigs are wreathed with bright golden yellow flowers, and many a garden arbour or cottage doorway is made the brighter for its presence from December till the end of February. Pruning should only be carried out after the flowers are over.

Fruits of *Citrus trifoliata*.—Several small fruits (containing seeds) of the hardy *Citrus trifoliata* (*Ægle sepiaria*) were sent by Lady Ilchester from Holland House to a recent meeting of the scientific committee of the Royal Horticultural Society. The fruits had been produced on a tree 9 feet high by 5 feet through, growing in the gardens at Holland House.

Mint Within Three Weeks.—This herb is readily forced, and is generally in much demand

throughout the year. If roots are lifted and placed in brisk heat with plenty of moisture, they will produce growth for cutting within three weeks.

A Useful Winter Salad.—A few roots of Chicory may now be placed in heat. The roots should be planted in large pots or boxes and placed in the Mushroom-house. Bury the crowns just below the surface of the soil. Any ordinary garden soil will be suitable, but it must not be too wet nor too dry.

YELLOW JASMINE GROWING OVER A COTTAGE DOORWAY.

A Pretty Rock Garden Creeper.—Such is *Pratia repens angulata*, both in flower and in berry. The small white Lobelia-like flowers spring out of a dense carpet of tiny foliage in late summer and early autumn. These in turn are followed by purplish pink berries, inclined to Pear shape, causing the plant to be of much interest and beauty in mid-November. Where space allows of growing large patches of this plant, the effect is very striking indeed.

Scabiosa cretica.—*Scabiosa caucasica* and its varieties are much-appreciated hardy perennials. For those who care for wild flowers, *S. cretica* also deserves a trial. This is a native of Greece and Sicily, where it grows on rocks and other barren places. It forms a small shrub from 2 feet to 3 feet high, with entire, whitish foliage. The flowers are not quite so deeply coloured as in good *S. caucasica*, but are large and showy, and no doubt it could be improved in time if taken in hand by some good cultivator. It should be planted in the driest places in the rockery, or in a wall, where it will not suffer from the wet and get all the sun and air that is possible. In Southern gardens it should prove a valuable addition, as it will flower very late in the season and early again in spring. It is easily propagated from seeds and likes any soil, especially that containing lime.

Wintering Globe Artichokes.—This vegetable not being quite hardy in most districts, it is well to have covering material ready to hand where it can be obtained conveniently, should a hard frost come. Stable litter or Bracken is suitable, and should be put round the foliage of each plant. Later on, when all the foliage has died down, it will require rearranging to make certain the plants are properly protected from frost.

Dianthus gracilis.—This charming little plant will one day probably take the same place among the Dianthi that *Viola gracilis* now holds among the Violas. It is a plant with which to work some of the most charming *Dianthus* pictures that ever graced a rock garden. The foliage is that of a super-healthy *D. cæsius*, and is quite as free and more continuous than that favourite species. The flower-stems are light and dainty, branching lightly, and carrying numbers of exquisite soft rosy pink blossoms. There is a glorious freedom about the dainty flowers and an absolute lack of "Dianthus uniformity," there being no stiffness or formality about the blossoms whatever, for they are poised like hordes of tiny pink butterflies upon the slenderest of stems. *D. gracilis* will be an "every garden" plant, as there is no uncertainty about its growth; and the rock gardener, be he specialist or amateur enthusiast, will assuredly not miss this plant once he has seen it in blossom.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Lilium giganteum.—I shall be happy to forward seed of this Lily to anyone who will forward a stamped directed envelope to me at Monreith, Wauphill, Wigtonshire.—HERBERT MAXWELL.

Plum Coe's Golden Drop.—If I were asked to give a list of the best dessert Plums, I should not hesitate a moment in placing the above in the first three. My acquaintance with this variety dates back to my childhood days, and I look upon it as one of the most richly flavoured when properly grown, and will remain on the tree fit for use longer than any other variety I know. Here we grow it on south, east and north walls, and it frequently lasts in fine condition well into November, thanks to its tough skin, which is a minor detail. My advice to your correspondent "E. R. M." is to root out his old, worthless trees and plant young ones, give them liberal and proper treatment, and I venture to predict he will then form a different opinion of this valuable Plum.—EDWIN BECKETT, V.M.H., Aldenham House, Elstree, Herts.

A Handsome Foliage Plant.—I am sending a photograph of *Dimorphanthus* (*Aralia*) *mandschuricus* *variegatus*, which is growing in my garden at Claygate. This interesting deciduous plant is worthy of extended cultivation. It is growing here on a clay soil on a warm south border. It receives no protection in winter, and has stood outdoors for six years. It flowers profusely every year, and bees are particularly fond of it. The climber in the background is *Solanum jasminoides*.—C. D. LANGWORTHY, Beaconsfield Road, Claygate.

Sauce for the Goose.—Yes! It was the account of the Lord Mayor's Feast that did it. I had not bought a solitary book, nor bulb, nor even a flower or plant of any kind for a year. But when I read how M.P.s (who preach economy to us) went and feasted, I forthwith ordered 100 Rose trees, 500 May-flowering Tulips, and several fruit trees; and—I here openly avow it—I feel better now!—ANNE AMATEUR.

Collecting Horse Chestnuts.—Re the leaflets issued by the Board of Agriculture and Fisheries, referred to in THE GARDEN, issue November 27, page 575, it may not be generally known that goats are particularly fond of Horse Chestnuts. Quite recently a visit to a friend revealed the fact that he kept six goats, and in the course of conversation he confessed that one of the "sorrows of his life" at the present time was that Horse Chestnuts had been so scarce this season. He showed me his store, some half-dozen bushels, only a quarter of the quantity he obtained last year. The Chestnuts are fed to the goats, whether in milk or not. I suggested the likelihood of the milk tasting of them, but an immediate sampling of both milk and butter convinced me that such was not so. The utility of the goat is beyond question, as witness the statements of a clergyman in the daily Press

recently that he saved £20 a year by keeping two goats; so it will be seen there is a great use for Horse Chestnuts. I will clinch the matter by stating that I myself keep a goat—a nanny, not yet in milk—and nothing does she "go for" more than the Horse Chestnuts.—HEATHER JOCK, Hants.

The Nankeen Lily.—This handsome Lily, so admirably spoken of by Sir Herbert Maxwell in his article on page 554, issue November 13, is a favourite in the South-West of Scotland, where it appears to do well, and where it is generally free from the attacks of the *Botrytis*, which is so disastrous to its reputed progenitor, *Lilium candidum*. I gather from Sir Herbert Maxwell's remarks upon this point that he has experience of the injury caused by the *Botrytis* on *L. testaceum*. It is, I think, very

DIMORPHANTHUS MANDSCHURICUS VARIEGATUS IN THE WARM CORNER OF A READER'S GARDEN AT CLAYGATE.

infrequent in the South-West of Scotland to see its ravages on the Nankeen Lily, although all too common in the same gardens on the Madonna Lily. A most unorthodox method of treatment which I have seen followed with surprising success is that afforded *L. testaceum* in a cottage garden in this county. In common with other hardy flowers in the border, it is lifted in spring, the border heavily manured with old stable manure, and the bulbs replanted, sometimes in the clumps, as lifted, and sometimes divided. The replanting is effected about the time of the growths showing above the surface, and usually in March or April. The Nankeen Lily seems to enjoy this treatment, and grows with a vigour and appearance of health which are the envy of many. I may add that the soil is poor and sandy naturally, having been at one time

reclaimed from the sea. There is a small proportion of lime in the soil, but none is added.—S. ARNOTT, Dumfries.

Is it Profitable to Grow Vegetables for Exhibition?—As an old exhibitor of twenty-four years' standing, I am a firm believer in exhibitions as means of stimulating interest in the cultivation of vegetables. They are object-lessons not to be lightly despised, but in order to get the splendid specimens seen at our shows much waste is incurred. For a proof, ask a market grower whether it would pay him to grow vegetables of the show type. Again, to grow twelve Leeks—six for a single class, six for a collection—I have had to use a piece of ground 15 feet by 4 feet 6 inches; get out a trench; raise my Leeks in heat or buy the plants; and put them out in May, all to be taken up at the end of September to exhibit. Now, on that same

space, at far less cost, I can get a crop of early Lettuce fit to cut in May and lasting till July; then, by filling up the same plot with Leeks I should get about 130 Lettuces and 130 Leeks. Compare this with a row of Leeks, at the most eighteen in all; my late Leeks coming in when most appreciated and useful. Fancy work must be put on one side for useful, and I assert with confidence that in the growing of show produce there is much waste of land, time and labour which can be put to a better purpose.—JAMES SMITH, Hon. Secretary, Harrow and Roxeth Allotment Society.

English v. Latin Plant Names.—

Your correspondent on this subject, issue November 27, page 585, has no doubt voiced the feelings of many. The giving of "English" names to new plants has lately run riot to a ridiculous extent. Nevertheless, there are some really "Old English" names which have acquired such familiarity (without the contempt bred by the new ones) that we could not do without them. Who but a botanical pedant would use the Latin (or Greek) names for Wallflower, Rose, or Lily of the Valley, for instance? A bed planted with *Cheiranthus Cheiri* edged with *Bellis perennis flore pleno alba* is not to be preferred to Wallflower edged with double white Daisy, as a description. Of such a pedant one might say that

"A Primrose by the river's brim,
Primula vulgaris was to him,
And it was nothing more."

And to extend the use of botanical names to the kitchen garden, which should logically follow, might lead to some curious results after the cook had given her orders to the gardener. Some of the old country names are very quaint. One old lady in a Welsh cottage called *Lychnis chalcidonica* "Scarlet of France," and another flower was "African Butters." It struck me that the use of buttons was probably less prevalent in Africa, at any rate among the natives, than in most other countries. At another cottage a Fern in a pot was named "Mary stitch 'em," which was evidently a polite rendering of *Poly-stichum*.—WALTER DE H. BIRCH, Walton-le-dale, Lancashire.

A WINTER-FLOWERING PLANT FOR THE GREENHOUSE.

Seaweed as a Manure.—Those readers who live on a coast where there is much Seaweed thrown up should not fail to use it this year as a manure. There are two chief sorts of Seaweed, but the best to collect is the shorter and softer kind. It should be collected in the autumn and mixed with half its own bulk of good fresh, strawy manure. It should then be thrown into a heap and turned over once or twice, and in about eight weeks it can be dug into any vacant ground. If stable manure is scarce, merely collect the Seaweed and let it rot in a big heap, but in this case a longer period (three months or more), had better elapse, to give it time to decompose. Seaweed is an excellent manure, and is largely used on the land near Flamborough and Bridlington, but there it is allowed to rot in small heaps on the beach above high-water mark for a few months before it is carted away. It is, of course, specially useful for Asparagus and Seakale, but Potatoes and green crops thrive excellently on ground which has been manured with Seaweed manure prepared as above.—E. T. ELLIS, *Weekwood, Ecclesall, Sheffield.*

Magnolia Delavayi.—Your correspondent Mr. E. Molyneux, referring to the flowering of *Magnolia Delavayi* at Bodnant Hall, Denbighshire, in THE GARDEN of November 27, asks the question whether this is the first note of its flowering in England? No, it is not, for it first flowered at the Coombe Wood Nursery of Messrs. James

Veitch in 1908, the plants having been raised from seed sent home by Wilson about ten years previously. Again, a flowering specimen about 6 feet high, and grown in a tub, was shown at Holland Park in 1913, when a first-class certificate was awarded it. This *Magnolia* was discovered by l'Abbé Delavay, but its introduction we owe to Wilson when travelling in China on behalf of Messrs. Veitch. It is strictly an evergreen, but is less hardier than the other evergreen species—*M. grandiflora*, whose flowers are so handsome. From this *M. Delavayi* differs in its larger leaves, with very long stalks, while the foliage is of a dull green above and glaucous beneath. The flowers are 7 inches to 8 inches across, cup-shaped, and of a creamy white tint. They also possess a pleasing fragrance. Though native of elevated regions in Yunnan, China, this is not hardy in the neighbourhood of London, but it does well against a wall.—H. P.

Buddleia madagascariensis.—The *Buddleias* are very vigorous growers in most cases, and this one seems to be one of the strongest. Although given in Nicholson's "Dictionary of Gardening" as from 3 feet to 6 feet in height, and in Cassell's as 10 feet, it is now about 45 feet high on the roof in the Tem-

perate House at Kew, where it is trained to one of the pillars near the centre of the house. The plant from which the photograph was taken has been in flower since September, and will continue to bloom until Christmas. The panicles are handsome, being from a foot to 15 inches long on the ends of the branches. The side growths are from 8 inches to 12 inches long. The flowers are of a pleasing shade of orange yellow, becoming paler towards the ends of the branches. The leaves are ovate-lanceolate, finely toothed, the upper surface a rough dull green, and a silvery white colour underneath. After flowering, the plant is cut back in spring to within a few inches of the previous season's wood. The shoots make from 6 feet to 8 feet of growth each season. The soil should consist of good loam with a little peat. The growth is always sufficiently vigorous.—W. L. L.

A RARE AUSTRALIAN SHRUB.

IN the latter half of the past century New Holland, or Australian, plants were more largely grown than of late. Many people may remember the fine specimens which used to be exhibited, and now are so rarely seen except at one or two of the large provincial shows, and mainly by one exhibitor. The illustration shows one of the quaintest of the *Hakea* family, which is a family so large that it takes more than three columns of a page in the "Index Kewensis" to enumerate all the species known and described. This plant has been collected at Port Jackson, near Sydney, New South Wales. With the present craze for English names for everything, I think anyone in search of an English name for it might reasonably call it the Barbed-wire Bush, for the leaves are as rigid and strong as wire, and at the end are provided with a very sharp spine. The illustration, three-fourths of the actual size, is reproduced from a water-colour drawing made from a bush growing on the Ile St. Honorat, off the coast of Cannes. It is said to grow about 15 feet high in its native locality. The flowers, peculiar in form, produced in pairs at the axils of the leaves, are white. It is also referred to as *H. gibbosa*. If it were grown in England, it would require the protection of a cool greenhouse, though possibly it might exist, if it did not thrive, in the South-Western Counties. J. T. BENNETT-POE, V.M.H.

HAKEA PINIFOLIA.

(From a drawing by J. T. Bennett-Poe, V.M.H.)

OUR NATIVE TREES AND THEIR CONGENERS.—II.

By W. BOTTING HEMSLEY, LL.D., F.R.S., V.M.H.

The Deciduous Element.—Excluding the Scotch Fir, now existing for the greater part only as a cultivated tree, our native woods and forests are very largely composed of trees having deciduous leaves, and are therefore winter-bare. These may be roughly divided into two classes, namely, into those having individually small, usually greenish or yellowish, unisexual flowers—both sexes, or at least the males, borne in catkins, usually preceding the leaves; and those having more or less conspicuous white or coloured flowers, developed later or with the leaves. Our catkin-bearing trees belong to three families, to wit, the Salicaceæ (Poplar and Willow); the Betulaceæ

9 inches wide, and catkins 4 inches to 6 inches in length. This would doubtless be the juvenile condition. *P. denhardtiorum*, the species found in British East Africa, is figured in the current part of Hooker's "Icones Plantarum" (plate 3050), where it is described as a deciduous tree, 60 feet to 80 feet high, abundant on the banks of the river Tana, from the sea-level up to an altitude of 1,500 feet. It is allied to *P. euphratica*, which is widely spread in warm districts of Western Asia and Eastern Africa. *Populus* is absent from the colder regions.

The Willow (*Salix*).—*Salix* is a genus numerous in species and of almost world-wide distribution,

genus is represented north of the Atlas Mountains in the Nile Valley, in the Soudan, in Nigeria, and in extra-tropical South Africa, as well as in Central Madagascar. Several very dwarf species inhabit the north Polar regions, where they constitute the greater part of the woody vegetation. *S. arctica* is recorded as being common everywhere, and it has been collected as far north as 82°–25'. *S. tetrasperma* is an Asiatic species widely spread in India (though absent from Ceylon), China and Malaya, descending to the tidal forests in Burma. *Salix babylonica*, the common, large Weeping Willow, is supposed to be a native of China. It is now widely spread in other countries, both in a wild and cultivated condition. It is one of the numerous alien plants naturalised in New Zealand, where it has become common on the banks of rivers. Indeed, it is stated that this and *S. fragilis* have given a new aspect to the vegetation of many river valleys, and one or both of these

species owe their increase in New Zealand to vegetative propagation. Willows generally differ from Poplars in having smaller, narrower leaves and erect catkins; but *S. magnifica*, a recent introduction from China, has leaves 9 inches by 6 inches, and very long catkins. Excluding Roses and Brambles, mostly of rambling habit, Willows are more numerous in species in the vegetation of the United Kingdom than any other genus of shrubby and arboreal plants, and they are more numerous and more generally disposed in Temperate and Arctic Europe and Asia than in America.

The Alder (*Alnus*).—*Alnus glutinosa* is the only species of Alder native in the United Kingdom. This species is widely spread in Europe, and it extends to North Africa and eastward to Japan, though unrecorded from China proper, where, however, other closely allied species exist. Altogether about a score of species are known, and they are spread all around the temperature zone of the Northern Hemisphere, and one or more species extend southward, in America, through Mexico and the Andes to Chile. One species is

BABYLONIAN WILLOW (*SALIX BABYLONICA*) BY THE WATERSIDE.

(Alder, Birch, Hazel and Hornbeam); and the Fagaceæ (Beech and Oak). They may be dealt with in the foregoing sequence.

The Poplar (*Populus*).—Poplars are spread all round the Northern Hemisphere, and are almost confined to temperate regions in a genuine wild state; but at least one species inhabits Southern Mexico, and one species occurs in British East Africa, in localities a little south of the Equator. They are mostly trees of large size and ample foliage. The number of species, usually given as below a score, has been augmented by later discoveries in Central and Western China, to something approaching thirty. *Populus lasiocarpa*, recently figured in the *Botanical Magazine* (plate 8625), is perhaps the finest species of the genus. It was first discovered by Professor A. Henry in Central China, and was found later by Mr. E. H. Wilson, who sent a living plant to Messrs. James Veitch and Sons, with whom it flowered in 1914. It is described as having leaves 14 inches long by

yet represented by very few species in the Southern Hemisphere, and absent from Australasia, the Pacific Islands and other large areas. The number of species of Willow is variously estimated as between 150 and 200, and there are numerous natural hybrids. Willows vary in stature from trailing or creeping shrubs, such as the native *S. repens* and *S. herbacea*, to tall trees, occasionally 100 feet high, with massive trunks. *S. fragilis*, *S. alba* and *S. caprea* are the largest kinds indigenous in the United Kingdom. Willows are characteristic in the vegetation of river banks and marshy ground of the temperate and cold zones of the Northern Hemisphere all round the world, but the genus *Salix* is represented in nearly all climates, reaching the altitudinal and latitudinal limits of flowering plants. At least half a dozen species inhabit Mexico, and of these one, *S. humboldtiana*, extends to the West Indies and southward to Brazil and Chile. Willows are rare throughout the great African region, though the

naturalised in South Africa. The common Alder attains considerably larger dimensions in some parts of its Continental area than it does in this country, sometimes reaching a height of 100 feet. According to Lester E. Ward, fossil remains of Alder, Beech, Birch, Oak and Willow have been discovered in the tertiary deposits of Australia, where no recent species of these genera are indigenous. If these identifications can be accepted, there must have been a considerable catkin-bearing element in the Australian vegetation of the tertiary period.

NARCISSUS VIRIDIFLORUS.

So few grow the curious little *Narcissus viridiflorus* that it is a pleasure to receive it from that ardent flower-lover, Miss Alice G. Bickham, Laurel Bank, Dunham Town, near Altrincham. It is worthy of a note, if only to remind readers of the existence of this uncommon, quaint *Narcissus*.

It is, one must admit, not a flower which will appeal to many, but there is about its quaint, long-tubed, small green flowers a touch of interest. Miss Bickham received her bulbs from Tangier, in Morocco; but the habit of the species is given in the "Dictionary of Gardening" as Spain, where it may have been introduced by the Moors. The leaves when fully grown are about a foot in length. The slender scape bears from one to four flowers, which have very long tubes and abbreviated perianth divisions. It flowers in November and December, and should, therefore, have the protection of a frame or cool house. S. ARNOTT.

[Through the kindness of Messrs. Barr and Sons, King Street, Covent Garden, we have recently seen this curious species. The small green flowers are of botanical interest, and their delicious vanilla fragrance compensates to a degree for their more or less inconspicuous character.—ED.]

ROSE MRS. F. DENNISON.

THIS Rose will be found to be one of the best of the 1915 Roses. It has been first rate right through the season with me here. I see the catalogue description drags in Mildred Grant, which is a pity, because the two Roses have not a single point in common beyond the fact that they are both exhibition Roses. Colour, shape, habit of growth, length, and continuity of flowering period, and fragrance, not the slightest resemblance of the one flower to the other can I trace in any one of these particulars. Then why drag in Mildred Grant?

It is damning a good Rose with faint praise to compare it to a Rose that is not everybody's money. In its proper place Mildred Grant is very well—but it is an exhibition Rose pure and simple, although the authorities at Kew had an enormous bed of it for years and may have still; but I always imagined that was intended as an object-lesson of how *not* to do it! So I should like to disabuse the minds of your readers, and assure them that Mrs. Franklin Dennison is not a bit like Mildred Grant. It is quite true that it is an exhibition Rose of excellence; but the habit of growth, the shape, the colour, the freedom of flower, and the fragrance are much nearer the ideal Rose than Mildred Grant is. I do not call Mildred Grant a white Rose, though the National Rose Society's official catalogue would lead one to suppose it is; but Mrs. Franklin Dennison is a good white on the outside of the petal, with yellow shading inside. It is an excellent grower, making many freely branching growths (instead of the solitary pole Mildred Grant prefers as a rule), each of which is capable of producing a fine flower.

Altogether it is a very useful addition to the increasing class of the "all-round Roses," and one that can be recommended alike to the garden Rose lover and the exhibitor. I was nearly forgetting to mention it was raised by Messrs.

S. McGredy of Portadown, Ireland, and is being distributed this year. It is named after the wife of one of our keenest amateur rosarians.

Southampton.

HERBERT E. MOLYNEUX.

THE BARBADOES PRIDE & ITS LATIN NAME.

I RECOGNISED an old Indian friend in your illustration on page 577, issue November 27, but she seems to have married again, as I never knew her under the name of *Cæsalpinia pulcherrima*. Surely her proper name is *Poinciana pulcherrima*, a sister of the gorgeous

pulcherrima is generally known as the dwarf *Poinciana*. It is also called 'Barbadoes Flower Fence,' 'Barbadoes Pride' and 'Bird of Paradise Flower,' while the Chinese call it 'Peacock's Crest,' and it is the 'Fleur de Paradis' of the French. It was introduced into Holland from Amboyna about 1670, and was growing under glass in the Chelsea Physic Garden about twenty years later. In Vol. XXV. of the *Botanical Magazine* there is an excellent drawing of it from a plant which had flowered in the collection of the Comtesse de Vaudes.

"The Sub-Order *Cæsalpinieæ* is subdivided into seven tribes by Bentham. Under Tribe II., *Eucæsalpinieæ*: 'Leaves 2—pinnate. Sepals free. Petals usually 5, subequal. Ovary-stalk free in the bottom of the calyx-tube; ovules 3—oo, rarely 1. *Pellophorum*, *Mezoneurum*, *Cæsalpinia*, *Hoffmansygia*, *Hæmatoxylon*, *Pterolobium*, *Gleditschia*, *Poinciana*, *Parkinsonia*.' The *Poincianas* are natives of the Tropics, and were named by Tournefort in honour of de Poinci, Prefect of the Antilles. They have been confused with the *Cæsalpinias*, but the calyx segments are valvate, whereas they are strongly imbricate in *Cæsalpinias*. There are only about six true *Poincianas*, viz., *boiviniana*, *compressa*, *elata*, *lutea*, *Playfairi* and *regia*; whereas there are probably some eighty or more *Cæsalpinias*. Swartz united *Poincianas* with *Cæsalpinias*, and he was followed by several authorities; but Gærtner and also Kew kept up the original division as now accepted. *Poinciana regia* is often confused with *Cæsalpinia pulcherrima*, but the latter may be readily distinguished by its much imbricated calyx segments, smaller flowers and very long exserted stamens."

ONE OF THE BEST OF NEW ROSES: MRS. FRANKLIN DENNISON.

Poinciana regia? I fetched down my old "Firminger," and found I *was* right: "*Poinciana Pulcherrima*—Peacock Flower—Barbadoes Pride—Flower Fence—Native name *Krishn-churun*." "Firminger" gives *Cæsalpinia* as quite different: "*C. coriaria*, a tree—American Sumach. *Grahami*, handsome very thorny shrub. *Paniculata*, a climber. *Sepiaria*, thorny shrub for fencing." *Cæsalpinieæ* is a Sub-Order under *Leguminosæ*, but as a name under that Sub-Order is confined to the four kinds I have quoted.

EDWARD M. HADOW.

Uffington Vicarage, Faringdon, Berks.

To these observations Miss Ellen Willmott, F.L.S., V.M.H., the writer of the previous note, kindly replies:

"The beautiful shrub illustrated in THE GARDEN of November 27 under the name of *Cæsalpinia*

free flowering and yet keep its height moderately low. It, however, requires quite as much room as a bushy *Abutilon*, for its branches are rather long, and they are clothed with leaves 6 inches to 7 inches across. The white flowers appear from near the points of the branches in large, round, pendulous heads, and are very attractive, for a plant of moderate size may at one time bear from fifty to one hundred heads of flowers.

Although not everybody's plant, it might certainly be grown by those people who have a large conservatory, temperate house, greenhouse, or corridor to furnish. The chief point to remember about its culture is that it should be cut back well in spring; then a succession of flowers may be obtained from July till early winter.

DOMBEYA MASTERSII.

It is only in those gardens where a large greenhouse is available that this plant can be grown with advantage, for in its native country, Tropical Africa, it grows into a moderate-sized tree. Fortunately, with some other members of the Order *Sterculiaceæ*, it stands cutting back fairly well; therefore it is possible to grow a plant to the necessary age for

DRY - WALL GARDENS.—II.

SOME SUITABLE PLANTS.

SUPPLEMENTING my last week's notes on dry-wall gardens, I now append lists of plants that with quite ordinary care can be successfully established in dry-wall gardens, and that call for the minimum of attention afterwards.

By way of preface, let me observe that the habit of each must be taken into account when planting; for instance, those that spread into hanging mats should not be placed too close above tufted or erect-growing kinds; rather reverse this arrangement, so that *Aubrietia*, for example, is placed below tufted *Dianthus* or *Armeria*. In this way the plants find room for healthy expansion, and it also frees one from the perpetual worry and annoyance of finding vigorous plants smothering out weaker or less happily placed neighbours.

ORCHIDS FOR A COOL HOUSE.

[In Answer to a Correspondent.]

IN a cool Orchid-house the average temperature during the winter months should be 50° Fahr., with a rise of 10° or so in summer. Blinds will be necessary to protect the plants from all strong sunshine, and if wooden lath blinds are chosen, they could also be utilised in frosty weather to economise fire-heat. The atmosphere must be kept more or less moist according to the season. This can hardly be overdone during hot, dry weather, but in autumn and winter much less moisture in the atmosphere will suffice. Ventilation must be afforded on all favourable occasions, but discretion should be exercised to prevent a direct draught passing over the plants. Both the top and bottom ventilators may be used during calm, moist weather, but at

other times only one set need be open. Moreover, it is better to open the whole of the ventilators (either top or bottom) an inch or so than one or two to their fullest extent. No one who does not employ a man with some knowledge of Orchids should attempt to grow them on a large scale without first feeling their way by experimenting with a few plants.

We now give a list of Orchids suitable for a cool

house. First and foremost is the chaste *Odontoglossum crispum*, with the many beautiful hybrids from this species. These should form the bulk, and if a number of plants are grown, a few will be in flower practically at all seasons. Other *Odontoglossums* embrace *O. Edwardii*, *O. Hallii*, *O. harryanum*, *O. Pescatorei* and *O. triumphans*. All of them flower in the spring and early summer. Hybrid *Odontoglossums* are very numerous, and include *O. amabile*, *O. percultum*, *O. ardentissimum* and *O. Rolfeæ*. As a general rule they are more easily grown, and bloom at various periods of the year. *Cypripedium insigne* varieties, *Epidendrum vitellinum majus*, *Cattleya citrina*, *Disa grandiflora*, *D. Luna*, *Cochlioda noetzliana*, *Sophranitis grandiflora*, *Zygopetalum Mackayi*, *Oncidium concolor*, *O. tigrinum*, *O. varicosum*, *O. ornithorynchum*, *O. macranthum*, *O. superbiens*, *Cymbidium lowianum*, *C. giganteum*, *C. eburneo-lowianum*, *Lycaste Skinneri*, *Masdevallia coccinea* varieties, *M. ignea*, *M. tovarensis* and *M. veitchiana grandiflora*.

The *Odontiodas* are hybrids between any of the *Odontoglossums* and *Cochlioda*, usually the scarlet *C. noetzliana*, and on account of their beautiful colour a few should be added. They require the same treatment as *Odontoglossums*, and the season of flowering depends upon the parentage. A few desirable kinds are *Odontioda Charlesworthii*, *O. Bradshawia*, *O. Cooksonæ*,

A LOW WALL PLANTED WITH ARABIS, GYPSOPHILA, IBERIS AND DIANTHUS.

Naturally, in dry walls of a semi-wild character, one rather enjoys the rivalry that is always more or less in evidence and is particularly noticeable when plants appear spontaneously, as they frequently do from seed deposited in the wall, either by the agency of wind or birds. No doubt the majority of these efforts rather upset our orthodox or preconceived notions of what we want. In some, however, a rare beauty is discerned, and their suggestiveness will always convey some truth to discerning minds. Except in walls of the latter description, I would suggest that planters be sparing in the use of such shrubby plants as *Helianthemum* and *Cistus*, unless boldly grouped in parts by themselves, for the reason that they soon attain unwieldy dimensions, the foliage prevents moisture falling upon plants below, and the roots set up arid conditions as far as they extend; hence plants of finer growth do not readily succeed in their company.

So many small gardens occur upon land that is of a chalky nature that I have thought it well to draw from my own experience of such a soil, and to mark by an asterisk in the foregoing lists such plants as will succeed without any special preparation of the soil; those unmarked will prove most satisfactory in a mixture of peat, loam and leaf-soil. On many limestone soils the amount of lime in an active state is often negligible, so that even granitic plants do not resent its presence.

Coombe Court Gardens.

THOMAS SMITH.

O. lambeauiana, *O. Vuylstekeæ* and *O. rosefieldiense*.

Annual repotting is not advised, and the soil is made up of *Osmunda* fibre, peat and chopped sphagnum moss in equal parts. The fibre and peat are pulled into pieces, and all the dusty particles removed by sifting. The repotting should be done when the new shoot is about to root, and, after the operation is performed, very careful watering is necessary until the roots take possession of the new compost, when the water supply can be increased. Ordinary flower-pots are used, and these must have one-third of their depth filled

FOXGLOVES AND OTHER FLOWERS
IN THE WILD GARDEN.

THE charming illustration from a photograph taken in the garden of Bishop's Hall Manor House suggest simple ways of bringing flower beauty to unlikely spots. Here, in a cool corner, the Foxglove is charmingly grouped, a little forest of flower-lined spikes mingled with Irises and many other plants that bloom at the same time. This getting away from beaten tracks adds to one's interest in gardening; there is no sameness, but a welcome variety in effect and the kind of plants used in

MAGENTA FLOWERS.

I WAS delighted to see a correspondent confessing in your issue of November 27 to a liking and a desire for magenta flowers. In some circles it needs as much moral hardihood to say that one likes magenta as it does to confess that one dislikes cold baths. Some folk seem hardly to like to use the word "magenta," as though it were unclean, and resort instead to "rosy purple." This seems as bad as softening "cold bath" into "soapy tepid."

FOXGLOVES, IRISES AND HARDY FERNS BY A WOODLAND PATHSIDE.

with drainage material. Thrip must be kept in check by vaporising the house at intervals, or the young growth will be damaged and progress retarded.

CAMPANULA GARGANICA HIRSUTA

At the present time dry-wall gardening is much in vogue, and it is quite right that it should be, as it is a most interesting way of growing hardy plants, and so many beautiful subjects can be accommodated in a limited space. This *Campanula*, with its trailing shoots, is quite a good subject where pale blue flowers are required.

the formation of such features. The Foxglove gives to the woodland a fresh beauty during the time of flowering, and perhaps our native wilding is as charming as any form of it; but the group called *Gloxiniæflora* is a distinct improvement upon the type; the name suggests the character of the flowers—*Gloxinia*-like—and the beautiful "bells" are white, with dark spots on the inside of the segments. The wild garden should be a garden of flowers—not, of course, set out in any conventional way, but groups here and there of Starworts, perennial Sunflowers and plants as graceful, flung, as it were, from the lap of Nature.

As a matter of fact, however, real true magenta is a very rare colour among flowers. *Callirhoe pulchella* is one of the truest examples, and the glossy, silky texture of its petals seems to enhance the glowing brilliance of the colour. The most splendid examples of magenta I have ever seen were *Bougainvillea* cascading over white walls in Madeira, and great trailing slabs of some *Mesembryanthemum* on the cliffs at the entrance to the harbour of Bonifacio. But, alas! these two effects cannot be repeated in this country, except, perhaps, on the "Cornish Riviera." I envy your correspondent her magenta border. I have often

thought I should like to try a border of strong magentas with a good many violets and purples and lilacs, a few pinks of the type of *Lavatera Olbia*—that is, with just a suspicion of blue in them—and perhaps a very few white flowers.

I will throw out a few suggestions, hoping that some of the plants I name may be of use to "Magenta." Comparatively few of them are the true colour, yet most or all of them are reds and pinks which would accord. Violets and purples I will not mention. For early spring at the front of the border there are two good *Aubrietias*, viz., *Fire King* and *Leichtlinii*. I believe elsewhere I have called them crimson. Well, they are the sort of crimson which will not quarrel with magenta. For late summer—also at the front—there is the cool-coloured *Epilobium Dodonæi*, only 6 inches or 9 inches high, and with plenty of character of its own. *Calamintha grandiflora*, also dwarf, is perhaps a little weak in colour, and not quite showy enough, though it might be tried. *Lythrum alatum* is dwarf and very pretty, of the right colour, but not always quite hardy. I used to grow *Dianthus Seguieri*, 9 inches to 12 inches high, and very rich in the colour wanted. Recently, from seed, I have obtained an inferior and rather mixed strain, and have given it up.

Lychnis Viscaria splendens plena is the plant I can more highly praise in this class than almost any other. It forms good tufts of dark, glossy foliage, and in June and July throws up plenty of flower-heads, solid and rich, like a double Stock, in colour strong and brilliant, 12 inches to 18 inches high. It is very easy to propagate—by division—at the proper time, viz., just after flowering. At other times I believe it is rather difficult to propagate. Another good edging plant for early summer is *Thymus Serpyllum coccineus majus*. This is a little taller in flower than the ordinary *T. S. coccineus*, and with larger flower-heads. The colour is a purer crimson than some of the flowers mentioned, but would be safe to use. A rather taller plant is *Betonica grandiflora superba*, 9 inches to 12 inches high, with very handsome heads of blossom. *Cortusa Matthioli* is the right colour, but might need cooler shade than is found in the front of the average border; and the same may be said of *Primula Veitchii* and *P. pulverulenta*, though they might be grown in rich, cool soil under these conditions.

Now for a few intermediate and tall plants. *Lathyrus latifolius*, grown on Pea-sticks, would give showy clumps of what might be called magenta pink; and if white flowers are to be admitted, the white form of this Everlasting Pea would be a useful companion to the type. *Lavatera Olbia* is pink, but a pink which I personally should admit to such a border, and near it I should grow the lavender Catmint (*Nepeta Mussinii*). The *Lavatera* must have plenty of room, for it makes a big bush 5 feet or 6 feet high and as much through. Also I should have *Lythrum virgatum* Rose Queen, with splendid summer spires of a strong magenta rose 4 feet to 5 feet high; and *L. Salicaria superbum*, a good form of the British Water Loosestrife, of a rather colder colour than the last. Some of the *Pæonies* might be included, and also the tall border Phloxes. Of the latter I would choose *Albert Vandal*, *Le Mahdi*,

Reichgraaf von Hochberg and *Rosenberg* among the stronger colours; and *Eugène Danzanvilliers*, a charming "print dress" lilac and white. I do not know what sort of a crimson *Phlox pilosa* is called in catalogues, but it is a colour I would put in the present border; height about a foot, and habit like that of *P. divaricata*. I think I would plant a patch of the two, mixed—lilac and cold rose. Another *Phlox* which might be included (for the very front of the border) is *P. subulata compacta*. It forms a solid mat of rich deep rose pink, and it has just that tone which would make it right among the magenta clan.

Of course, there are several *Pentstemons* and *Carnations* of a magenta tone; but here, I fear, I cannot advise as to exact varieties. The same applies to the hybrid *Gladioli*. There are some

A HOME-GROWN BUNDLE OF GIANT ASPARAGUS.

very strong, rich colours among them of magenta persuasion, and probably described in catalogues as crimson purple or rosy purple. But there is a splendid species of *Gladiolus*, viz., *G. byzantinus*, of a fine ruby red—pigeon's blood ruby—which should certainly go into the magenta border. It grows about 3 feet high, flowers about midsummer, and with me is quite hardy. The well-known *Bergamot* would be too hot a red, but *Monarda violacea superba* should certainly be included; height about 2 feet to 3 feet. *Verbena venosa*, height 12 inches to 18 inches, very free-flowering, not quite hardy, is superb. How shall I describe the colour? Reddish violet? It is better not to try to be too accurate, but it is a grand plant for our purpose. Personally, I should grow it near or mixed with some such plant as the dark *Heliotrope*. A rich reddish magenta when in flower is the improved *Honesty* (*Lunaria biennis*

atrococcinea). It is, of course, biennial. The truest magenta flower of which I can think is *Callirhoe pulchella*, an annual. Another annual to grow at the front of the border would be *Mesembryanthemum tricolor*, with starry Daisy flowers, the rays a good tone of rose, with a white zone at the centre. And by "rose" of course I mean a tone of rose which will go with magentas and violets, as opposed to salmons and yellow pinks.

My last suggestion may come as a surprise to many—*Cineraria stellata*. Sow the seeds under glass about January or February, grow on in pots, and plant out in the border in rich loam about May, giving plenty of room, and water well in dry weather. The plants will flower through the middle and late summer, and astonish all beholders. A good mixed strain will do, for no *Cineraria* that I can think of would give discord

in the "magenta" border (except the terracotta *C. Matador*, which is not a stellata variety). I grew *Cineraria stellata* in a herbaceous border seven or eight years ago, and the plants remained magnificent even after the autumn frosts had made the Michaelmas Daisies look shabby.

Stevenage.

CLARENCE ELLIOTT.

GIANT ASPARAGUS.

THE immense sticks of *Asparagus* that one sees in the London shops are usually imported at high prices from Paris. They may be as easily grown in this country as they are around Paris,

provided the plants are grown in suitable soil and manured liberally when bearing. Many people prefer these large sticks, and they are known in Paris as *l'Asperge d'Argenteuil*. Many sticks attain a circumference of 4½ inches to 5 inches, and weigh from 10oz. to 12oz. each. These fine sticks are grown chiefly at Argenteuil and in the environs of Paris, but are also grown in numerous private gardens in other parts of France.

The market growers around Paris plough their ground about 12 inches to 14 inches deep in autumn, after having given a dressing of well-decayed manure of about 12 yards (square) per acre. (The manure is usually sold by the mètre cubic in France.) This is left in as rough a state as possible during winter to benefit from the frost.

In wine-growing districts *Asparagus* and Vines are frequently grown in alternate rows. When this is so, the *Asparagus* is planted about a yard and a quarter apart. In places where it is grown by itself, the single plants are put about a yard apart both ways. They are grown like this in private gardens as well.

The best results are obtained from a moist, sandy loam; but where the soil is heavy, very good results are obtained when a quantity of gritty or sandy soil is dug in and mixed well with the soil. Before planting, all large stones are collected and removed from the beds. Great care is exercised to procure plants from a reliable stock, as much depends on this. On the vexed question as to whether one, two, or three year old plants are best, it is difficult to express an opinion. Many first-class growers make their beds from one year old plants only, and I have seen some

splendid results from these beds. From older plants, of course, cutting commences earlier. In the case of one year old plants, cutting commences four years after planting, the fifth year giving a full crop. In the warmer districts planting takes place in March, but in cold places the end of April is early enough.

When planting is commenced, a trench is taken out about 4 inches deep and 18 inches wide. The soil is put on either side and the bottom of the trench made firm, as Asparagus prefers a solid base. The roots are spread out and covered with fine good soil, pressed well around. Then a stick is put in a few inches away to protect the young growths and to mark the place. Enough soil is then pulled down from the sides to cover the plants to a depth of 4 inches. The following year some more soil is added in the same manner in spring, with a mulching of well-rotted manure. This is continued for two years more, when the trenches are filled with the surrounding soil and the bed is level. In the winter the soil is pulled back from the clumps, and about 9 inches of fine soil placed over the plants each spring. For the first few years, crops may be planted between, and weeds are kept down by hoeing. In dry weather heavy soakings of water are given, where possible. W. L. L.

THE ROYAL LILY (LILIUM REGALE).

By SIR HERBERT MAXWELL,

OF all the floral treasures which diligent collectors have discovered in Western China during the last twenty years or so, none excels, very few equal, this in beauty. It is well named *Lilium regale*, the Royal Lily, for it is a truly splendid flower. When it was first introduced to this country at the close of last century, it was named *L. myriophyllum*, in allusion to the densely crowded linear leaves that clothe its 3-foot stem, but it was soon recognised as quite distinct from Franchet's Lily of that name. Its affinities are with *L. Brownii* and the newly discovered *L. Sargentæ*; but *L. Brownii*, though peerless in beauty, is one of the most difficult of its race to keep in cultivation; whereas the Royal Lily, grown in well-drained soil with a plentiful admixture of ground lime, displays the constitution of a common Martagon. It flowers three weeks or so earlier than *L. Sargentæ*, and although of inferior stature (Mrs. Sargent's Lily exceeded 5 feet in height with, me this year) is of more graceful habit and more delicate colouring. The ground of the blossom is alabaster, flushed with rose outside and with clear yellow inside; the anthers are golden, as distinct from the orange brown of *L. Sargentæ*.

The Royal Lily has proved perfectly hardy, so far, in the open without protection at Monreith, except that a few of the young growths were cut by a sharp frost in May of the present year, which injured many other choice things.

THICK V. THIN TRAINING OF FRUIT TREES.

HOW the training of fruit trees, both under glass and in the open, in gardens and orchards varies! Evidently there is much diversity of opinion among fruit growers as to the best method to adopt.

Gardeners, as a body, are prone to allow their trees to produce and retain too much wood. It seems strange that Apple trees, Peach trees, or even Vines are often allowed to retain so many branches, and yet produce but a moderate quantity of fruit. Yet such cases are common, and no amount of reasoning seems to have any effect. How often do we see Peaches under glass almost a thicket of growth, when half the number of shoots would produce better results.

or Pear tree, Red Currant or a Gooseberry tree. If ten main branches are sufficient to produce a full crop of fruit, why have twenty? Too many persons fail to see why espalier-trained Apple trees give more regular crops than bushes or standards. A moment's reflection should prove that there is not the overcrowding in an espalier-trained tree there is in a bush. Bush Apple trees are probably more neglected in a systematic pruning than any other kind of tree, if I omit open wall Peaches or Morello Cherries.

Young bush Apple trees often make vigorous growth and at times give a little fruit; and instead of their being corrected at the root and the thinning of the current shoots in summer, they are allowed to retain all their growth until the autumn, when the trees are again hard pruned, especially their leaders, the result the following year being more vigorous growth still and less promise of fruit. If those who manage their trees on what I

A MAGNIFICENT DISPLAY OF THE ROYAL LILY (LILIUM REGALE) AT WARLEY PLACE.

It is the same with Peach trees on open walls. Too often trees are found where the leaves of one branch overlap doubly those of the next shoot, and if the latter is examined in the autumn it will be found that the bark is quite green instead of being red. If three properly matured current season's shoots will produce all the fruit necessary next year to give a full crop of fruit all over the tree, why should a dozen shoots be retained in the same space?

It is the same with Vines under glass. If a single rod can carry twelve bunches, why should that rod be allowed to have double that number of spurs? Again, it is not uncommon to see spurs furnished with two or more shoots. This is absolutely unnecessary, except, perhaps, in the case where there is a gap on the opposite side of the rod and two on this particular spur are retained for the purpose of filling that space. Take, again, a bush or a standard grown Apple

have tried to show as a wrong principle would meditate for a moment as to the function the leaves perform for the welfare of the tree, I think they must see at a glance it is impossible for the leaves to mature under such circumstances as an almost entire absence of light. If the leaves do not mature, how can they perform their function of supply to the wood in the forming of fruit-buds? I venture to say that nineteen out of every twenty successful Grape growers act on the principles I have noted, namely, allow abundant space between the rods, spurs and growth shoots.

Too many gardeners were trained under a wrong formula in fruit growing; that is why they cannot realise the advantage of opposite methods.

How, then, can we expect amateur cultivators to grasp all the correct principles with their restricted opportunities? E. MOLYNEUX.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Peaches.—Trees which were started early in November may be subjected to a slightly higher temperature, but it must be borne in mind that the Peach is very impatient of artificial heat, especially during the early stages of growth. Forcing should be done chiefly by making the best use of sun-heat. Admit air during the forenoon during bright weather, but close the house while the sun is full on it. Spray the trees with lukewarm rain-water on fine mornings, and damp all bare surfaces in the house as often as necessary. Commence disbudding the trees when the buds are about an inch long, removing about one-third of the buds at the first operation. This important work should be spread over several weeks, so that the trees may not receive a check. Before the trees come into flower, fumigate the house with a nicotine compound. During the flowering stage the temperature should not fall below 55°, and the atmosphere must be kept dry. Pollinate the flowers before noon, paying special attention to those on the upper side of the trees.

Young Vines.—Vines which were planted last season may now be pruned. If they have made satisfactory growth, the main rods may be cut back to 2 feet or 3 feet; but if the growth is weak, they should be cut back to two or three buds. Vines intended for planting in the spring must be cut back before the end of the year. When dry, the cut surfaces should be painted with styptic to prevent bleeding. Plunge them in ashes outdoors till a week or two before they are required for planting.

Plants Under Glass.

Chrysanthemums.—The main batch will now have passed out of flower, and attention must now be given to the propagation of a new stock of plants. Worthless varieties will have been noted, and these should be discarded. When suitable cuttings are available, they may be inserted in pots or boxes and placed in a propagating-case. Any varieties which are shy in producing cuttings may be placed in one of the fruit-houses which have just been started.

Lachenalias.—These will now be making good progress, and must be placed on a shelf in the greenhouse. At no time must they be hurried by placing them in too much heat. As the pots become filled with roots, some form of stimulant will be necessary.

Coleus thyrsoides.—This beautiful plant is now developing its flowers, and with careful attention to watering and feeding, it will continue to flower throughout the winter. It is essentially a stove flowering plant, but it will continue to flower quite satisfactorily in the greenhouse or conservatory provided the temperature does not fall below 50°.

The Flower Garden.

Fuchsias.—Young plants which were struck in the autumn should now be potted up into 3½-inch pots and grown on in a moderately warm atmosphere. If standards are desired, some of the most promising plants should be selected and grown on in the same way as Heliotropes. The dwarf plants will require to be stopped at suitable intervals.

Wall Plants.—Many climbing subjects may be planted now, provided the weather is open. It is necessary to thoroughly prepare the ground by deep cultivation and manuring. Nearly all climbing plants may be purchased in pots. The following are a few subjects suitable for growing on walls: *Ceanothus*, *Passiflora cærulea*, *Polygonum baldschuanicum*, *P. multiflorum*, *Escallonia*, *Cratægus*, *Cydonia*, *Cotoneaster*, *Jasminum nudiflorum*, *Chimonanthus fragrans* (the last two are now in full flower), *Ivies* in variety and ornamental Vines.

Protecting Bulbs.—It will be wise to keep a careful watch on bulbs which have been recently planted. Rats and mice will do very serious damage to various kinds of bulbs when other food is scarce. Mice are easily caught in traps, but rats are not so easy to deal with. Where poison can be used with safety, this is the

best means to destroy these latter pests. Pheasants are known to be fond of Tulip bulbs.

The Hardy Fruit Garden.

Raspberries.—These may be planted as soon as they can be procured from the nursery. The ground should be trenched and manured, and should it be of a heavy, retentive nature, a quantity of burnt garden refuse or wood-ashes will be beneficial. Should the ground be very wet at the time of planting, a little dry soil from the potting-shed will facilitate the work. Plant firmly, and when finished cover the roots with a coating of short litter. The variety *Superlative* is one of the most reliable. Autumn-fruiting Raspberries have done remarkably well this year. These need replanting every season to grow them to perfection.

The Kitchen Garden.

Early Potatoes.—Hot-beds must now be made up on which to place rough frames for the forcing of early vegetables. The tubers need not be planted till the New Year, but if the soil is placed in the frames and covered with glass, it will be in good workable condition when planting-time arrives. Good crops of Potatoes may be grown in pots or boxes. They may be placed in a fruit-house which has just been closed.

Celery.—It will be necessary to place protecting materials over the plants during times of severe frost. A little dry Bracken will answer the purpose well, but it must be removed as soon as mild weather appears. The Celery disease has been unusually prevalent in this district.

Herbs.—Supplies of herbs may easily be kept up by placing a few roots into heat at regular intervals. Sorrel should be lifted and potted into large pots; roots of Tarragon and Mint may be planted in boxes, as also may Chives. Another sowing of Basil may be made as soon as the old plants show signs of exhaustion.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Flower Garden.

Herbaceous Border.—This border should be cleared of most of its occupants about every fourth year and trenched, putting in a liberal quantity of farmyard manure. Some subjects, such as *Pæonies* and *Lupines*, resent frequent disturbance, and should not be interfered with. The roots of all plants must be protected while the trenching is being done, and, when possible, only portions should be done at a time, in the event of frost or snow interfering with the work. If every advantage is taken during open weather, this work will be completed before early spring, leaving more time for other work during that busy season.

Bedding Stock.—Plants of the more tender subjects, such as *Ageratums*, which are being kept to produce cuttings later on, should be kept near the glass to prevent them becoming weak and drawn. Although very little water is required for most of the plants during the short days, they must not be allowed to suffer from the want of it. *Geraniums* are subjects which are very easily injured by too free a use of the watering-can.

Violas and other subjects of a more hardy character being wintered in frames must receive proper attention regarding ventilation and protection during severe frost. Where the soil in which they are growing has become green on the surface or stagnant, it should be freshened up with a small fork. Decaying leaves or cuttings which have damped must be at once removed.

The Kitchen Garden.

Potatoes.—Those being kept for seed purposes should be looked over at intervals to remove any doubtful or diseased tubers. During spells of severe frost it will be well to see that the Potatoes are sufficiently protected. The same remark applies to other Potatoes which may be stored in outdoor pits; these are certain to need an additional

covering of straw or similar protecting material while severe weather continues.

Brussels Sprouts.—During very wet winters Brussels Sprouts are sometimes injured through the decay of the foliage. The plants should be looked over, and any decaying leaf-stalks removed. The tops of the plants must not be taken for use until all the Sprouts have been gathered.

Cauliflower.—Young plants wintering in frames must not be allowed to damp off through want of proper or sufficient ventilation. Even during frosty periods advantage should be taken near the middle of the day to open the lights, if only for a short time. As slugs are troublesome, soot or some gritty material must be sprinkled around the plants to prevent these pests from doing harm.

Fruit Under Glass.

Early Figs.—To get the earliest Figs next season, some pot Figs should be started now. A mild hot-bed of stable litter and leaves should be made up in the house or pit where they are to be grown, plunging the pots to the rims in this after making sure that the heat in the bed has commenced to decline. Use the syringe on bright days, and when water is required at the roots use it in a tepid state; but if the roots are in a proper condition when the plants are brought indoors, water should not be required for some time. Should the plants require top-dressing, and perhaps the pots may already be well filled, additional soil may be added after placing zinc bands around the rims of the pots.

Fruit-Houses at Rest.—With the exception of the early vinery and Peach-house, all should be resting. This period is equally important as the growing season. Abundance of air and all possible light are needed, so that no tree should be overshadowed in any way by plants or other subjects. Heat must only be allowed to circulate in the pipes when there is any danger of them being split by frost.

The Hardy Fruit Garden.

Training and Pruning Wall Trees.—Periods of mild weather should be chosen for this work, as it is only under reasonably comfortable conditions that the operator can perform this work satisfactorily. All previous ties should be examined and renewed where necessary. No more young wood than is absolutely necessary ought to be trained, as overcrowding is a common cause of many failures. Newly planted trees should not be tied or nailed into position until the soil has settled, which will not take place for some little time after planting.

Plants Under Glass.

Calanthes.—Most of the deciduous varieties are in full flower, and must be kept in a fairly dry atmosphere, yet not too warm. A minimum temperature of 60° should be the rule. As they pass out of bloom the flowering stems must be cut over; then the bulbs placed on a dry shelf in the stove or intermediate house, where they will get complete rest for a time. Care must be taken to keep them dry. Where space is a consideration, the bulbs can be shaken out from the pots and placed closely together in boxes, covering the roots with sand.

Violets.—Growth is very slow at present, and the production of bloom is consequently retarded. As many blooms damp off before opening, the plants should be gone over occasionally and the flower-buds lifted up carefully to the top of the leaves, where they will open quicker with the benefit derived from the light and exposure. Where the soil has become green, the surface should be stirred up with the point of a stick or small hand-fork. Abundance of air must be given on all favourable opportunities, but covering up will be needed during frost.

House Washing.—It is very important that all light possible should find its way to the plants unobstructed. Near large towns it is necessary to wash the glass outdoors several times during the course of a season. In the interests of cleanliness for the health of the plants, all glass and woodwork indoors should be scrubbed down with warm soapy water.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

"HUMOGEN," OR BACTERISED PEAT.

A REVIEW BY F. J. CHITTENDEN, F.L.S.

The Spirit of the Soil.*—One of the most remarkable results of scientific investigation into the soil has been the vindication it provides of the cultural processes adopted by generations of the best cultivators, ignorant though they were of scientific facts. In no direction is this more apparent than in the aid cultivation gives to the helpful nitrogen-fixing and nitrate-making bacteria. But ever since the discovery of these organisms the problem of getting even more out of them than the best cultivation succeeds in doing has attracted many minds. The book under review is an account of the latest effort to turn them to profitable use, and gives "an account" (as the subtitle states) "of the nitrogen fixation in the soil by bacteria and of the production of auximones as promoted by bacterised peat."

I should like to take the book chapter by chapter and discuss each, but that is impossible within the limits of a review, and I must content myself with making a general comment upon its subject; but before doing so I should like to say how much I have enjoyed the perusal of the book, for I have rarely read a more lucid and interesting presentation of a somewhat difficult and often technical subject, and never, since Tilden's "Chemical Philosophy" intrigued my imagination, have I come across so clear an exposition of elementary chemical conceptions as the author gives in Chapter IX. This chapter does not seem necessary to the argument, but is rather an interpolation unconnected with those preceding and following it; it is, nevertheless, a delight to read.

The main object of the book is to give an account of bacterised peat or Humogen, and of the remarkable effects it is destined to produce. Humogen is the result of a search by Professor Bottomley, who is its patentee, for a medium in which to cultivate nitrogen-fixing organisms. He has, he believes, found it in peat. Now "peat" means many things to different minds, and it is, in this case, a very different material from that usually called peat by gardeners. It is, indeed, nothing more nor less than the peat-moss litter which is used so much in towns for bedding horses. In its fresh condition it is not suitable for the development of the bacteria, but Professor Bottomley moistens it and inoculates it with humifying bacteria (the nature of which he has not divulged), which are allowed to grow in it for some days at a suitable temperature. The result of their growth is a great increase in the amount of the soluble humates in the material, and it is these soluble humates which Professor Bottomley believes serve to encourage the growth of the nitrogen-fixing bacteria. The humifying bacteria are killed off by steam, and a mixture of the nitrogen-fixing germs, *Pseudomonas radicola*

(the germ which produces nodules in Peas and Beans) and *Azotobacter chroococcum* (the chief nitrogen-fixer living free and fixing nitrogen in soils), is added. After keeping for a few days at a suitable temperature, Professor Bottomley finds that the nitrogen content of the mass has greatly increased, and, after drying, the material is fit to be used as a fertiliser. It is to be added to the soil, where it is said to enhance the nitrogen-fixing capacity, and to increase the growth and yield of crops of all kinds. This increased yield is (according to Professor Bottomley) not entirely or even perhaps mainly due to the available nitrogen added, but to certain bodies produced by the activity of the bacteria, called auximones. Auximones

Bottomley tells us he takes full responsibility for the results Mr. Knox has described. The book may therefore be taken as authoritative. The author is firmly convinced, it is evident, of the value of the material, and, indeed, he is hardy enough to state his conviction that Nitro-Bacterine (which he also devotes much space to and which many will remember proved a failure in general application in this country) is worthy of use, since it gave *some* good results, ignoring the very general distribution of the *Pseudomonas radicola* which it is intended to add to the soil—a distribution almost universal in the soils of our country. He gives many instances of good results obtained by the use of Humogen, and though these will not for the most part satisfy scientific scrutiny as evidence, and some of them are totally inadmissible—as, for example, where four Potato tubers (weight not stated) yielded 2lb. 10½oz. of Potatoes when grown in sterilised moss watered with Humogen extract—yet they are sufficient to show

A SURPRISE IN CONNECTION WITH HUMOGEN IS THAT IT INTENSIFIES VARIEGATION AS WELL AS DEVELOPMENT.

The Coleus plant on the right received humogen, while the one on the left had the usual potting compost.

are said to take the place in plants which vitamins occupy with regard to animals. Feed an animal with all the materials in ample quantities which chemical analysis tells us are necessary, and the animal fails to thrive, unless provided also with minute quantities of certain elusive substances to which the name "vitamines" has been given. It is a fascinating idea, and quite possibly a true one, that similar substances are necessary for plants, and Professor Bottomley believes that he has discovered them. At any rate, the most active material in promoting growth appears to exist in very small quantities in the Humogen, as shown by the water-cultures described. Whatever it may be in the Humogen—nitrogen, auximones, or something else—in many cases very marked results have followed its use.

The author has been, he tells us, deeply interested in the experiments Professor Bottomley has had in hand for the past eight years. He has taken no part in carrying out the experiments, but Professor

that the material is worth very careful trial as a fertiliser. He admits that some experiments have shown no good results, but alludes to only one, of which he gives a partial account. This method of presenting a case for Humogen detracts from the value of an otherwise admirable book.

I have seen remarkable examples of increase in growth due to Humogen, and I have seen other cases where the difference in crops on treated and untreated ground has been practically negligible. Before the material can be confidently recommended to take the place of farmyard manure, such differences must be explained. Does the explanation lie in the sentence quoted below (from page 154), and are the different samples sent out of different values? "Experience shows that different samples of peat show large differences in the quantity of soluble humus that they yield." Or may there not be "accidents" during its manufacture which result in considerable differences in the final product? The raw material

* "The Spirit of the Soil," by Gordon D. Knox, with a Foreword by Professor W. B. Bottomley. 8vo, xiii. + 242 pp. London: Constable and Co., Limited, 1915; price 2s. 6d. net.

is a complex one, its manufacture is complex, and it is to be added to a very complex mixture, the soil. Until the results it gives can be depended upon as surely as those following the use of, say, farmyard manure, it is not likely to be acceptable to the general public.

Humogen, or bacterised peat, has given sufficient good results to justify extended experiment, and I hope that all who can will experiment with it, remembering, however, that peculiar difficulties surround garden experiments, and that one increased yield following its use does not justify a high estimate of the value of Humogen, nor does one failure justify its condemnation. Conditions which have not been taken into account may explain the one or the other.

Professor Bottomley has made a discovery of considerable scientific interest, and I believe of great potential value. I understand he has offered to hand over the discovery to the nation, and to forgo all his patent rights in favour of the nation for the period of the war. Exactly how this generous and public-spirited offer is to be given effect to is not yet settled; but when details are forthcoming and the material available for distribution, I hope it will be widely experimented with by gardeners, for we are badly in need of a substitute for farmyard manure.

ANSWERS TO CORRESPONDENTS.

THE GREENHOUSE.

INFORMATION ABOUT ASPIDISTRA (E. W.).—The full name of the plant grown as *Aspidistra* is *Aspidistra lurida*, a native of China, whence it was introduced in 1822. In a state of nature it grows on the partially shaded outskirts of forests. This gives a clue to its successful cultivation, for it should not be grown where fully exposed to the sun. The variegated-leaved form originated as a sport from the ordinary green kind, but the date thereof we are unable to give. There is also a scarce variety (punctata) in which the variegation consists of small dots over the entire leaf. We presume you have seen the curious flowers of the *Aspidistra*, which first make their appearance as small knobs on the surface of the soil. When expanded they are starry in shape and of a dull purplish brown colour; hence the name of *lurida*. Though to an ordinary observer there appears no likeness between this plant and the beautiful pure white *Madonna Lily*, they are botanically nearly related, both being members of the Order *Liliaceae*.

INJURY TO FERN (B. B.).—The Maidenhair Fern is very badly attacked by scale; the worst attack, indeed, we have ever seen. You might try cutting down all the fronds completely and dipping at intervals in a mixture made by kneading some flowers of sulphur into a handful of soft soap and dissolving it in $1\frac{1}{2}$ gallons of hot water. After the mixture has cooled, dip the plant; but it is probable it is too badly attacked to recover.

ROSE GARDEN.

LIQUID ARTIFICIAL MANURE FOR ROSES DURING THE WINTER MONTHS (Maida Vale).—Even if your trees are well established, it is a mistake to feed them with artificial manure such as you suggest during the winter months, when the plants are more or less dormant. The majority of growers wait until growth is active before attempting to feed Rose plants. The National Rose Society's Annual for 1915 has a symposium by half a dozen well-known experts that would prove interesting reading to you. It can be obtained from the Secretary of the National Rose Society for 2s. 6d., and is the best work on the subject.

LATERAL GROWTHS ON ROSES (R. L. S.).—This term is used when the small side shoots that spring from the main branches are referred to. They vary in length and stoutness. Those of small, thin, short growth upon rambler and climbing Roses are usually cut back to one or two eyes; whereas the stronger ones are retained from 4 inches to 12 inches, and even more in length.

WICHURIANA ROSES FOR BANK (A. W. Martin).—Dorothy Perkins would be about the best variety you could plant. Lady Gay is perhaps better in foliage, and the new Chatillon Rambler would flower earlier. Ethel, too, is very fine, but rather addicted to mildew. American Pillar is grand, both in foliage and bloom; but you could not mix it with any other very well. For real beauty of foliage you could not surpass this variety. Shower of Gold is very beautiful as regards foliage, but you would not obtain such a fine effect in bloom as from Dorothy Perkins or American Pillar.

FRUIT GARDEN.

TIME OF RIPENING OF APPLES AND PEARS (E. M. H.).—With regard to the time of ripening of Apples and Pears, there is not, and cannot be, a hard and fast rule, seasons, soils, aspects, positions and localities playing their part in hastening or retarding this process, last year specially demonstrating this fact. In the case of Pears this was specially noticeable, many varieties being weeks, and some even months, out of their scheduled time of ripening. As regards the quality and flavour of both Apples and Pears, the conditions above mentioned are responsible for extraordinary variations in this respect. The question of culture also, whether good or bad, as well as the age of the trees, are important factors in determining this matter.

APPLE BISMARCK (Enquirer).—No doubt you have the true Bismarck. Your description is good and correct. Usually the fruit is in season from October to Christmas.

BLACK ROT IN APPLES (Colonel H. M.).—The Apples appear to have been attacked by the fungus which causes black rot, *Sphaeropsis melorum*. This is not a common disease in this country, though we have seen it on previous occasions. The same fungus causes leaf-spot of Apples, and at times canker of the branches. We recommend you to spray the trees in the way we have several times recently recommended for scab, and to prune out all cankered growths if there are any in the tree, protecting the wounds so made by painting them with lead paint or with Lysol.

KITCHEN GARDEN.

SEED POTATOES TO STORE (Potato).—Keep your seed Potatoes in a cool, airy, fairly light position. An outbuilding or an empty room, for instance, would do, provided it is cool enough and at the same time frost proof. Place the tubers in single layers on dry boards, or in shallow boxes. You must guard against their being excited into growth before natural growth takes place in spring, and then let growth come on as slowly as possible so that the sprouting growth shall be short and sturdy; at the same time give each tuber more room. Evidently the place yours are in is too warm, by their sprouting now. Remove these sprouts and place the tubers in a cooler place. Seed Potatoes will rot, whether cut or not cut, before a crop of new ones are formed. When planting-time comes round, take special care in handling the tubers not to injure the sprouts; it is from these that the crops will proceed.

FAILURE IN CARROT GROWING (S. P. W.).—Our correspondent says that the whole of his Carrots were spoiled by a white worm when they were about the size of a lead pencil; this in spite of the land having received a good dressing of quicklime the winter before. All the gardens in our correspondent's neighbourhood are similarly affected, so that the trouble is a serious one in that part. The most effective remedy would be to burn the top crust of the soil to a depth, say, of 6 inches; it is not so difficult or expensive a matter as many people think. Make a good body of fire, with a bit of coal to start with, afterwards adding any available wood and garden refuse that will burn; then cover the fire over with a crust of soil 7 inches or 8 inches deep, let it remain on the fire until it gets so hot that you are satisfied nothing can live in it, then take it off. Stir up and add fuel to the fire, and cover over again with soil until the soil of the plot on which you propose growing Carrots has all been done. It would be better to do this shortly before the Carrots were sown than now. Another way is to dig the ground now, scatter soot and lime freely over the soil as each furrow is turned over, and add a very small scattering of common salt (a handful only over a turned furrow 3 yards long).

MISCELLANEOUS.

BRUSSELS SPROUTS RIDDLED WITH CATERPILLARS (A. L.).—There is no good method safe to be used for clearing caterpillars off Brussels Sprouts except hand-picking. You might try spraying with water at 115° Fahr., or spraying with a $2\frac{1}{2}$ per cent. salt solution. Each of these presents some hope of success, but neither is certain.

NAME OF PLANT.—*Boris*.—*Pyraecantha coccinea*.

SOCIETIES.

GLASGOW AND WEST OF SCOTLAND HORTICULTURAL SOCIETY.

UNDER the auspices of this society a lecture on "Alpine Flowers," with lantern illustrations, was given in the Religious Institute Rooms, Buchanan Street, Glasgow, on the evening of December 1. Mr. D. G. Purdie, chairman of directors, presided over a large attendance. The lecturer of the evening was Provost S. Arnott, Sunnyside, Maxwelltown, who discussed the subject in a practical manner, dealing first with the question of "What is an Alpine?" and pointing out that horticulturally the term included dwarf plants suitable for rock gardens, and was not confined to those which were, strictly speaking, true alpine flowers. He dealt with the position, material and construction of rock, wall and moraine gardens suitable for the cultivation of alpine flowers, passing on to give a rapid review of a number of the most suitable genera of alpine flowers. The lecture was illustrated by a number

of lantern slides, showing a considerable variety of suitable subjects, the selection of slides being specially strong in Campanulas. The lecture was well received, and on the call of the chairman, Provost Arnott was accorded a hearty vote of thanks, the hope being expressed by the chairman that the lecturer would come another year. A good specimen of *Begonia Gloire de Lorraine* was exhibited by Mr. H. Reid, Ruchill Hospital Gardens. The chairman intimated that this lecture brought to a close the short series arranged by the society, and expressed his gratification at their success under the adverse circumstances caused by the war.

DUMFRIES AND DISTRICT HORTICULTURAL SOCIETY.

THE annual meeting of this society was held in the Wesley Hall, Dumfries, on the evening of November 27. In the absence, through illness, of the president, Provost S. Arnott, Mr. A. W. M'Alister occupied the chair. Provost Arnott sent a letter expressing a desire to be relieved of the duties of president on account of the pressure of his municipal work; but it was resolved to appoint a deputation to ask him to accept office again. The financial statement was submitted by Mr. J. L. Armstrong, secretary and treasurer, and was of a satisfactory nature, showing a balance at the credit of reserve of upwards of £50, with one on ordinary account of upwards of £5 after paying over £55 to war relief funds. Subject to Provost Arnott reconsidering his decision, he was reappointed president, and the following other office-bearers and members of committee were appointed: Vice-presidents—Mr. W. Hutchinson (Terregles Gardens), Mr. J. Maxwell-Gray and Mr. A. W. M'Alister; committee—Mr. J. Learmont, Mr. J. Croall, Mr. J. Cormack, Mr. T. Hunter, Mr. W. Brown, Mr. J. B. Crichton, Mr. O. Robertson and Mr. W. Edgar; secretary and treasurer—Mr. J. L. Armstrong.

OBITUARY.

W. ATLEE BURPEE.

By the death of Mr. W. A. Burpee, which occurred recently in Philadelphia, we mourn the loss of an American horticulturist who was particularly well known in this country. He was a Britisher by birth, for he was born in Canada, and was very proud of this fact. It was in connection with the Sweet Pea and the National Sweet Pea Society that he was best known in this country, and he was a familiar figure at the shows, trials and festive gatherings of this society. His eloquence will long be remembered, for he was a bright and interesting after-dinner speaker. Moreover, he had the power of making true and valuable friendships, and to those who had the privilege of calling him friend their loss will be very great, for he was a man of immense intellect whose chief attributes were love, sympathy and charity.

SAMUEL BIDE.

It is with deep regret that we have to record the death of Mr. S. Bide, the head of the esteemed firm of Messrs. S. Bide and Sons, Limited, Alma Nurseries, Farnham, who passed away on November 25. Mr. Bide was much respected in the horticultural trade, and he was looked upon as an authority on Roses, forest trees and vegetable crops, such as Seakale and Asparagus, which are extensively grown at Farnham. For some time Mr. Bide had been ailing, and his end was doubtless hastened by the death of his wife, which occurred only a few weeks ago. His funeral took place at Hale Parish Church on the 29th ult., amid every token of respect from a wide circle of relatives, friends and employes.

National Rose Society.—The annual meeting, which is of so much interest to rosarians, will be held in the Connaught Rooms, Great Queen Street, Kingsway, W.C., on Tuesday, December 14, at 2.30 p.m.

* * The Yearly Subscription to THE GARDEN is: Inland 6s. 6d.; Foreign, 8s. 9d.

THE GARDEN.

No. 2300.—VOL. LXXIX.

DECEMBER 18, 1915.

NOTES OF THE WEEK.

Marriage of Corporal Herbert Cowley.—On December 8 the marriage took place between Mr. Herbert Cowley, Editor of *THE GARDEN*, and Miss Elsie M. Hurst, the only daughter of Mr. Samuel J. Hurst of Kingston. The wedding was solemnized in the Parish Church, Kingston-on-Thames, the Rev. Joseph Jacob very kindly officiating, and the occasion was favoured by an exceptionally bright day. Mr. Cowley joined the 12th London Regiment (The Rangers) on the outbreak of war, and has twice been wounded at Ypres. A shrapnel wound on the knee-cap has left him unfit for active service. Our readers will join us in wishing Mr. and Mrs. Cowley a long and happy future.

The Prickly Heath (*Pernettya mucronata*).—This is unquestionably one of the most beautiful of all berried shrubs for autumn and winter effect. The berries are usually of a bright rosy purple, but there are varieties with crimson, white, pink, purple black and intermediate colours. The twiggy sprays of this low-growing shrub are useful for decoration in the house, while the plants look very cheerful in the garden at this season. This Heath is perfectly hardy, belonging to the Natural Order Ericaceæ.

Kew Gardens Protest.—In opposition to the declared intention of the Board of Agriculture and Fisheries to make charges for admission to Kew Gardens, Councillor Filby moved a resolution of protest at a meeting of the Richmond Town Council on December 14. In view of the great educational value of Kew, the tax on visitors is greatly to be deplored. Rumour has it that the public will be admitted at a charge of 2d. before noon and 1d. after noon, while certain days are reserved for students, artists and photographers, who will pay an admission fee of 6d.

Show of Hardy British-Grown Flower Bulbs.—For the encouragement of home industries the Council of the Royal Horticultural Society have consented to the holding of an exhibition at Vincent Square of hardy home-grown flower bulbs on August 1, 1916, in order to demonstrate the excellence to which such bulbs can be grown in Great Britain and Ireland. For the purposes of this exhibition corms and tubers, such as Crocuses, Anemones and such like, may be considered as bulbs. The schedule includes classes for amateurs and the trade. It is now ready, and may be had on application to the Secretary,

Royal Horticultural Society, Vincent Square, Westminster, S.W.

National Rose Society.—Owing to the serious illness of Mr. Cook, the treasurer of this society, the annual general meeting, which should have been held on the 14th inst., was unavoidably postponed.

Death of the Hon. John Boscawen.—Just as we are closing our pages for press we learn with

The Fruiting of *Xanthoceras sorbifolia*.—The fruiting of this shrub is unusual, but Miss Mellish, Hodsock Priory, Worksop, writes that it has fruited very freely against a south-west wall in her garden this summer. It is of considerable interest to learn of out-of-the-way shrubs fruiting, such items being of sufficient interest to place on record.

Agathæa cœlestis.—This charming South African plant is one of the few blue flowers that comes freely in the winter; in fact, at almost all times of the year. To obtain the flowers at this season of the year, the young growths should be pinched during the summer; these will then produce quantities of the dark blue flowers for a long time. As pot plants they will be found most valuable, while a few of the flowers with Ferns in specimen glasses are very pleasing in a cut state.

Sweet Lavender.—In aid of the War Horticultural Relief Fund, Miss Swan of Warlingham distributed packets of Lavender at the fortnightly meeting of the Royal Horticultural Society on December 7, and at the Carnation Show on December 8, at the Royal Horticultural Society's Hall, Vincent Square, S.W. The Lavender had been grown in her field at Warlingham and was made up into various devices of her own design. This opportunity of supporting the fund met with a ready response, there being many purchasers for the pretty and distinctive Christmas gifts, such as may be afforded even in war-time.

The Garden Varieties of *Ceanothus*. Much more attention is now being paid to these beautiful autumn-flowering shrubs. One of the earliest hybrids introduced was *Gloire de Versailles*, and it is no doubt largely due to the success of this variety that they owe their rise in popular favour. Their season of flowering extends from July until November, and even now they are quite bright. There are many shades of colour, varying from white and pink to rich rose, pale blue and deep purple. A

selection of sorts in addition to *Gloire de Versailles* should include *Indigo*, *Georges Simon*, *Perle Rose*, *Gloire de Plantières*, *Ceres*, *Arnoldii*, *Fantaisie* and *Marie Simon*. The giving of awards of merit this autumn to *Fantaisie* and *Georges Simon* by the Royal Horticultural Society will draw more attention to these beautiful shrubs.

A WELL-BERRIED SPRAY OF THE PRICKLY HEATH (*PERNETTYA MUCRONATA*).

deep regret of the sudden death, on the 12th inst., of the Hon. John Boscawen of Tregye. He was at one time a member of the Council of the Royal Horticultural Society, but he will be best remembered in connection with the gardening section of the Royal Agricultural Society, the success of which was largely due to his untiring efforts, and the Truro Daffodil Society.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Climbing Plant from a Tuber.—I am sending a specimen of a climbing plant which grows from a tuber. Will you please tell me the name of it through the medium of your paper?—PRESTON. [The plant sent for identification is *Tropæolum tuberosum*, or the Peruvian Nasturtium. The tubers are freely produced, and are said to be edible when boiled like a Potato. It is only half-hardy, and tubers should be taken up in the autumn and stored away like Dahlia roots.—ED.]

An Indian Garland Flower.—I am sending a photograph of a very beautiful spike of *Hedychium gardnerianum*. The flowers are lemon coloured and very fragrant. I find that it does best when planted out in the conservatory, for its roots do not like to be confined in pots. I have heard it stated that this species is nearly hardy, but have never seen it growing outside and should not care to risk my plants, which each year flower so handsomely, to the fickle climate of an English winter.—O. M. G., *Hants.*

Actinidia chinensis.—Your correspondent "B." asks what is the best aspect for *Actinidia chinensis*. In my experience, shade is essential. I have one over 20 feet high on a north wall here, and another over 30 feet high, with a lateral spread of 15 feet, on a west wall, but so shaded by large trees on the south and west that it is never touched by the sun. It is important to remember that a male plant should be placed near the larger female type if fruits are desired, though I have never yet obtained them here.—L. H., *Nuneham Park, Oxford.*

Mice in the Garden.—The correspondent who wrote you about his yellow *Antirrhinum*s being eaten by mice may be interested to hear that the mice in my garden also pick out yellow plants, but in my case they are yellow *Crocus* corms. I have a long border planted with clumps of *Crocus* in four different colours at intervals down its full length. Last winter the yellow *Crocuses* were picked out all down the border, scratched up and eaten. The result was, of course, that last spring there was hardly a yellow flower to be seen, while the blues and the whites had increased very much, having been there about four years. We caught seven of the mice. They were of a brown colour, with very large eyes and ears and long tails. We are replanting the yellow *Crocuses* this autumn, and I am curious to see if the mice will pick them out again. There are many other bulbs in the border—*Snowdrops*, *Daffodils* and *Tulips*, none of which is ever touched, and which come again year after year.—C. L. Cox, *Tanllan, Dolgellay.*

The Origin of the Loganberry.—Mr. E. A. Bunyard's note on the Loganberry is valuable as giving us rather more detail about its origin than we had before seen in print. But he seems to me to raise larger doubts than necessary about its parentage, which it surely bears pretty plainly on its face, or, perhaps I should say, in its qualities. Given the certainty that the Dewberry was its mother, it is surely also certain that a Raspberry

was its father, for it could not conceivably have inherited its undeniable Raspberry flavour from any other *Rubus*. I have for many years interested myself in the Rubi, and out of all that we know, including the large recent additions from China, I have never found one with the remotest affinity in flavour to the Raspberry. On this account, and because of other obvious differences, I cannot believe that any pair of Rubi excluding the Raspberry could produce the Loganberry, or that the Dewberry could possibly "mutate" into the Loganberry. The theory of mutations is as yet in such a tentative stage that it is well not to summon it into court when explanation is possible

nearer to our Blackberry. I may mention that here we propagate the Loganberry not by the slow method of pegging down its tips, but by cutting the ripened canes into lengths of about 9 inches and burying them all but two eyes. We find no difficulty in striking them.—G. H. ENGLEHEART, *Dinton, Wilts.*

Is it Profitable to Grow Vegetables for Exhibition?—I have just been reading in the pages of *THE GARDEN*, issue December 11, Mr. James Smith's remarks on the above, and I must confess I am rather puzzled to understand his grounds for writing as he does, as he distinctly states he is an old exhibitor and a firm believer in exhibitions for stimulating interest in the cultivation of vegetables, after which, in the same short note, he condemns the same as a waste of land and labour which could be put to a better purpose. Now, I suppose none will deny but what any form of exhibiting does entail a certain amount of extra care, trouble and expense; but to hundreds of exhibitors it gives much pleasure as well as stimulates industry. I paid a short visit to the Smithfield Cattle Show on Tuesday, December 7, and I remarked what a pity it would be if such a show was abandoned, as the amount of interest in and trade done at such a show is remarkable. The same applies to every form of competitive exhibition, and especially in relation to vegetables, as without such friendly rivalry I doubt very much if we should be in possession of such splendid types of vegetables as we have at the present day. In many cases market growers strive to succeed in growing some of the finest vegetables, and I am prepared to say these rank among the most successful. By all means crop and intercrop every piece of ground available, especially during such anxious times; but surely one should not be denied if he thinks fit to obtain the finest produce that the land will give. I know of no more enthusiastic secretary than Mr. Smith, and I have had the pleasure on many occasions of seeing the splendid produce which has been brought together under his care, but I certainly fail to understand his views as related in the issue of *THE GARDEN* mentioned.—EDWIN BECKETT, *V.M.H.*

Lapageria rosea alba.—It may be of interest to your correspondent "K. G. J." to know that the specimen referred to as growing in the Jardin des Plantes, Paris, flowered there for the first time in Europe in 1855. For its general distribution in this country we are, however, indebted to Messrs. James Veitch,

whose collector, Richard Pearce, of tuberous *Begonia* fame, sent home seed and living specimens from Chile in 1860. According to "*Hortus Veitchii*" it flowered with Messrs. Veitch for the first time in 1862, and was exhibited with *Lilium auratum*—at that time rare—before the Royal Horticultural Society on July 2 of that year. The typical *Lapageria rosea* was first introduced by Mr. Richard Wheelwright, who sent a plant to the Royal Gardens, Kew, in 1847. The next year plants were received from William Lobb, then collecting in Chile on behalf of Messrs. Veitch, and from that time it gradually made its way into cultivation.—H. P.

FRAGRANT AND LEMON-COLOURED FLOWERS OF *HEDYCHIMUM GARDNERIANUM*.

without it. Many years ago in Lynton in North Devon, on the river bank just above the well-known "Watersmeet," I found, in a thicket of Blackberries and wild Raspberries, growing together, an obvious and excellent hybrid between the two, a fruit smaller than the Loganberry, but sweeter, and with the advantage of pulling off the core when gathered. I have once or twice seen the same intermediate on our Wiltshire Downs, where wild Raspberries and Blackberries commonly grow together, but they were inferior. We used to be told that the Loganberry is Blackberry × Raspberry, and it certainly looks and tastes like such a hybrid. Possibly the American Dewberry is unlike our English Dewberry and

BANKSIA INTEGRIFOLIA, HANDSOME IN FLOWER AND FOLIAGE.

A Late-Flowering Climber.—In a note to my letter of November 16 about the Passion Flower (*Passiflora carulea*) on my house being then in full bloom after severe frosts, you called it "remarkable," so it may interest you and others to know that, in spite of the still harder frosts and bitter weather at the end of last month, it is still (December 5) in full flower, and the thick foliage and large trails are as green and luxuriant as in summer. It is a curious thing, too, that the blossoms last, fully expanded, from two to three weeks. I have never seen Passion Flowers which remained open in summer for more than two days; in fact, that always seems their weakness, from a decorative standpoint. That the plant likes a south aspect or sunny situation is evidently quite a mistake, as one I put on the south side of a building, in a walled garden, with its roots alone shaded, is now, like all usually behaved Passion Flowers, yellow and dried up.—A. LA T., *Oxfordshire*.

Border Carnations.—I was glad to see Mr. J. L. Gibson's article on Carnations in THE GARDEN, issue November 27, page 579. To my mind he makes a remarkable statement *re* Dora Blick, undoubtedly a beautiful colour, but the petals are on the small side. My experience of this variety is that it has a remarkably strong stem, so much so that, when showing, it is necessary to wire the stem so as to bend it down and outward to show towards the judge, instead of facing the ceiling. Mr. Gibson has mentioned some good varieties and makes a bid for criticism. However, I should be glad if he will consider the following selection. Selfs: Bookham White or Farthest North, Daffodil or Mrs. Elliot Douglas, Fujiyama or General French, John Knox or Gordon Douglas, Elizabeth Shiffner or Dora Blick, Madge or Daisy Walker, Miss Rose Josephs or Irma. Fancies: Linkman, Pasquin, Lieutenant Shackleton,

Lord Steyne, Skirmisher. J. J. Keen, Fancy. Picotees: Mrs. J. J. Keen, Onward, Pure Gem, Queenie, Professor Burstall, Exquisite. If THE GARDEN could get a ballot of the best Carnations from, say, twenty of the best amateur Carnation growers, it would be most interesting, and I think the foregoing list would be well in the running. Most of these varieties have received highest awards at the various Carnation shows, and several have not been seen at the London Show yet. General French is the best scarlet I have seen; the same applies to Professor Burstall as a Picotee, and J. J. Keen and Pasquin as fancies.—H. W. FROSTICK.

Modern White Sweet Pea.—A good deal of correspondence has been published in the gardening Press this year on the respective merits of modern white Sweet Peas, and, as far as I am concerned, I have plumped for Constance Hinton every time. Mr. E. R. Janes of Wroxton Abbey Gardens gives his opinions in a contemporary, and they are surely worthy of consideration, for Mr. Janes has "done things"; he has almost swept the board at the leading Sweet Pea shows during the past season. Mr. Janes dismisses Norvic with a mere mention of its

name. At this I am not surprised, for, although I have seen Norvic very finely shown, the proof of the pudding is in the eating, and when I obtained seed from the leading distributors of it this year, it turned out unsatisfactory, inasmuch as a lack of rogueing was apparent, or else it shows a liability to sport. Anyway, I had pink and cream as well as white in the row. Mr. Janes has rather more to say about Edna May Improved, but this variety, which owes its reputation principally to the booming it has received from Mr. Walter Wright, evidently takes quite a minor place in Mr. Janes' affections; he practically sums it up as possessing length of stem and little other merit. For Constance Hinton, on the other hand, he has nothing but praise, and his experience coincides with mine and with that of numerous other growers with whom I have discussed it. We do not know what the future may give us, but at the present moment I pronounce Constance Hinton to be at the top of the tree. As grown here it has been a real beauty, of the purest white, with solid, lasting flowers of ideal shape, and so beautifully and gracefully placed on the stem that it would stand as a model in this respect for Sweet Peas of any other colour or variety.—F. HERBERT CHAPMAN, *Rye*.

BANKSIAS.

THESE Australian plants have handsome foliage and interesting flowers, and they are useful plants for a large house. Among the best species are:

Banksia collina.—The plant shown in the illustration below is about 6 feet high, and is now plentifully dotted with its curious and pretty yellow flowers. This species comes from the hilly districts and has small leaves, which terminate abruptly, as if bitten off. It was introduced in 1788 and is a handsome and interesting plant.

B. integrifolia has larger leaves of a dark green colour on the upper surface. The under surface is a silvery white. The plant from which the photograph was taken is about 16 feet high, and is now in flower in the Temperate House at Kew.

B. serrata is a dense-growing, handsome plant, having deeply serrated leaves about 5 inches to 6 inches long. It rarely flowers in this country. The flowers are red and about 6 inches long.

B. verticillata.—This has large leaves of a pleasing shade. They are dull green on the upper side and silvery white underneath, and have the midrib of a brownish tint. When the plants are tall—and they grow to a height of 18 feet or more—the leaves, arranged in whorls of fours or sixes, are very pretty as one looks at them from below.

Cultivation.—These plants may be propagated by cuttings inserted in sand and placed under a

BANKSIA COLLINA, NOW FLOWERING IN THE TEMPERATE HOUSE AT KEW.

bell-glass. The cuttings should be taken off at a joint, and only the leaves that are to be below the soil must be removed. The cuttings should be put in sand only deep enough to keep them in position. They do not like much bottom-heat. Belonging to *Proteaceæ*, they require ample drainage and careful watering. The pots ought not to be too large, and should have one-third of the depth filled with carefully arranged crocks. The roots run down among these and seem to thrive better there. The soil should consist of equal parts of good peat and loam, with plenty of sharp sand. *Banksias* do not like too much heat nor to be kept too close. If over-watered, or if they become too dry, they rarely recover. W. L. L.

RIVIERA NOTES.

A FEW notes this winter, when so few folk have dared to leave their native land for the South of France, may be of gardening interest. The summer has been a cool one, and very dry till October came in, when there was a great drop in the temperature, followed by rain for the rest of the month. This cold has retarded autumn growth and autumn-pruned Roses greatly, so that Oranges are still far from ripe at the end of November, and unless December and January prove unusually fine and warm, neither *Poinsettias* nor the Tree *Salvias* (*S. frutescens*) nor the Tree *Dahlias* will come to perfection. After four days of cold wind and almost frosty nights in the middle of November, the weather has become very fine and warm again, so gardens that are not deprived

of their masters and gardeners are fast recovering their winter beauty.

Nerines are becoming more cultivated, and that useful late-blooming bulb which is known as *N. Mansellii* in England and *N. tardiflora* out here is now in full flower. *Cypripediums* of the *insigne* type and its best forms, such as *Sanderæ*, *Chantinii* and others, are in beauty. *C. fairrieanum* and *C. leeanum* are, if possible, brighter in colour and freer in flower than under glass in England. Grown plunged in sand under the shade of an extra thick Olive tree, they require no care save an occasional watering all through the year; and I see a *Lælia anceps* that was tied to an Olive branch two years ago is thriving and throwing up more than one strong flower-spike, which will, however, need very good December sunshine and warmth to make it expand freely before the new year comes in.

It is sad to see the neglected *Carnation* terraces, though here and there a few blooms are grown for the local markets; and the terrible prices of coal and fuel make it quite impossible for any forcing of *Roses* under glass, which has been so great an industry latterly.

That fragrant winter-flowering shrub, *Buddleia auriculata*, scents the air, and *Freylinia cestroides* will carry on the fragrance throughout January. That most lovely of all the *Acacias*, *A. podalyriæ-folia* (which calls for a handier and more intelligible name), is one sheet of fairy-like blossom on silvery sprays of growth, and will last until *Acacia baileyana* comes into flower in the month of January. The well-known "*Mimosa*," *Acacia dealbata*, will wait till February is well in, with the Almond trees in their glory. *Bignonia Cherère* and *Bougainvillea Sanderæ*

are at their best now. *Bignonia venusta* is full of flower-bud and has already a few gorgeous orange heads of flower open, but with good weather it is at its best in the month of January, and is most lovely when scrambling through the branches of the old *Rose Lamarque*, pruned so that both shall flower together on a south wall in midwinter.

This autumn, for some inscrutable reason, I have never seen such glorious blooms of that capricious golden *Rose George Schwartz* as are now open. Grafted on various stocks to see which will prove the best, this year, at any rate, *Rosa bracteata*, the *Macartney Rose*, has proved the ideal stock, while the *indica* major stock, which has often given good results, is nowhere. I wish someone in England would bud it on *R. bracteata* under glass and give it a trial; it is still by far the most sumptuous of all rich golden *Roses*, with a fragrance all its own, but, being so capricious, it is little known or grown.

Roses generally are not promising this winter, and *Carnations*, as I have said, are far below their old standard; so we shall have to fall back on the flower of the country, the *Anemone*, which is now springing up strongly after the abundant autumn rains, and will in due time delight our eyes with its vivid and glorious colouring in early spring. *Violets*, I regret to say, are everywhere less good than usual, as they are more dependent on summer care, and cannot be left untended as can the *Anemone*. E. H. WOODALL.

THE JAPANESE SNOWBALL TREE.

THE *Viburnums* include many beautiful shrubs, such as the *Guelder Rose* and its companion the *Wayfaring Tree*; while, at the present

time, the fragrant ever-green *Viburnum Tinus* or *La urustinus* is flowering in almost every garden of repute in the country. But of all the *Viburnums* none can excel the Japanese Snowball Tree (*V. plicatum*) for effectiveness. In May it is smothered with clusters of white flowers resembling those of the *Guelder Rose*. It may be planted now, and no garden is complete without it, for it is one of the six most beautiful shrubs for English gardens.

THE JAPANESE SNOWBALL TREE (*VIBURNUM PLICATUM*).

THE "DAFFODIL YEAR BOOK."

"A NOVICE" is not pleased with what he calls my *ex cathedra* review of the 1915 issue of this book. A reviewer seldom pleases unless he writes only to please, and he necessarily writes *ex cathedra* when the Editor has put him into the chair. But let me assure "A Novice" that, despite more years at the study of this flower than I like to count, I feel myself yearly more and more of a novice as regards knowledge which can be formulated into working rules. It may, however, interest him to compare my somewhat longer experience in the matter of artificial and self fertilisation with what he gives as his own, and to read it into what I was constrained to say about that long list of "successful" but unflowered crosses.

"A Novice" has in six consecutive years obtained from Mme. de Graaff artificially fertilised an amount of seed which is enormously preponderant over the yield from the same plant left alone. Now I have grown Mme. de Graaff, chiefly for seed, for over twenty years, ever since its first introduction, and for many years in breadths of thousands, and have found its apparent law of seeding to be exactly the converse of this. Careful depollination and brush fertilisation will give me perhaps one pod in ten flowers, while a 50-yard bed left alone will set nearly every flower. This is so invariable in my field that we always cut off the fading bloom in our stock beds of this variety in order to relieve the bulbs from the strain of seed bearing. We seem to have evidence that this large seed crop is due to self fertilisation, seldom to pollen carried from other varieties. I have sown seed (1) from these "left alone" beds, (2) harvested and sent me by a friend in Surrey who does no crossing, and in both cases the resulting flowers show no cross at all, but are evidently spontaneous reproductions of Mme. de Graaff itself. They mostly show a marked tendency to revert to the yellow or bicolor Ajax, which was one of Mme. de Graaff's parents, the white blood reappearing in a much smaller proportion. Moreover (3) the percentage of seeds from flowers which have "missed fire" in the artificial crossing gives precisely the same range of form and colour.

Other raisers have reported to me their similar experience. Therefore the necessary inference is that Mme. de Graaff is in many, possibly in most, localities strongly self fertile. Here in South Wilts we have reason to believe that in exceptionally warm, dry springs it is apt to fertilise itself before the flower opens. I have had abundant proof that this is so with Poeticus under such conditions, and a thirty years' experience has made me think, though I should be slow to dogmatise after 300 years, that this occurs with Daffodils at large. I do not question "A Novice's" carefulness and accuracy, but his figures do not invalidate what I have written. I must point out to him that out of his six years' crossings of Mme. de Graaff, begun only so recently as 1910, a very small fraction can as yet have flowered, and he cannot yet know whether any or how many of the parent flowers were self fertilised. Messrs. Cartwright and Goodwin, whom he quotes, were new-comers to hybridising work when they printed

their assertion on this subject, and could scarcely have had material enough of their own raising to demonstrate it. Such statements carry probability only when based upon the investigation of large quantities over long periods. For these

PRIMULA SINO-LISTERI, A RARE SPECIES OF DOUBTFUL HARDINESS.

reasons I fear I must still maintain, in a quite kindly and Pickwickian sense, that it is absurd to call a cross successful before the arrival of the flower. Even in this sense I do not apply the term to Dr. Lower's own local and particular work, but only to the citation of his work as a universal guide for the Year Book's readers.

"A Novice's" reading is hardly as careful as his gardening. He says: "Mr. Engleheart assumes it to be impossible to depict a suggestion of colour differences in a photograph by the use of colour screens." I wrote the exact opposite, viz.: "It seems that colour can be satisfactorily rendered only by over-expensive colour photography or by some method of screening which it has here been found impracticable to use," i.e., that though the method is well known, there was apparently some reason against using it in the present issue. I am all for the continuance of the series of flower photographs, while maintaining that a "white all over" representation of a highly coloured flower is meaningless. Its colour is its point, and it is pointless if its colour is omitted.

Colour is yearly becoming more and more important in the appraisalment of new Daffodils. In form we have nearly reached perfection; in colour we are still in the crude elements. A faithful rendering of the more subtle and delicate colouring will, perhaps, always be impossible, but the stronger colouring, e.g., a red cup against a white or yellow perianth, can be suggested even in black and white, and no doubt the editor of the Year Book will in future contrive this.

G. H. ENGLEHEART.

PRIMULA SINO-LISTERI.

THIS interesting plant is the Chinese form of a Himalayan Primula which is known as *P. Listeri*. As in the case of the Sikkim Primrose (*P. sikkimensis*) and its Chinese form (*P. Pseudo-sikkimensis*)

ensis), the plants from the latter region appear to be more amenable to culture in this country, being more vigorous in habit and with larger flowers. The plant here illustrated was collected by Forrest for Messrs. Bees, Limited, in 1908. It was found growing on the Tali range in Yunnan. Closely allied to the well-known *P. obconica*, it has been found that it does not possess the irritant hairs peculiar to that species, which is a decided advantage. The acutely lobed leaves, on long petioles, are produced in rosettes, and in early spring the white flowers are borne in trusses. These last for a long time in good condition, making it a good plant for the cool house. Although plants stood outdoors last winter in a sheltered position, this species is of doubtful hardiness, and its usefulness is confined mainly to the cool greenhouse. It is easily raised from seed or propagated by division, and may be grown well in a cold frame potted in light, rich, sandy loam. W. I.

A BEAUTIFUL GREENHOUSE SAGE.

SALVIA LEUCANTHA is a very distinct plant and makes a handsome subject for the greenhouse at this season of the year. This Mexican Sage is shapely in habit, with narrow leaves which are deep green on the upper surface, but covered with a fine down underneath, while the flowers, which are produced in long spikes, are quite woolly in aspect. They are of a mauve rose colour, and against the white woolly down, are very pleasing and worthy of a place in all greenhouses at the present time.

A HARDY ARUM LILY.

CALLA ÆTHIOPICA.

COMMONLY known as Arum Lilies and generally met with when grown as greenhouse plants, Callas are invaluable and easily grown; but it is to their uses as water plants and used as clumps in the herbaceous border that I would refer. Colonies of these, when seen flowering profusely, are a pretty sight, and where a sheltered position can be found for them, a trial is well deserved. They are, I think, much hardier than many imagine, and seek protection during winter below the surface of the water. They bloom, too, at a season when other flowering aquatics are none too plentiful, and, once planted, are no further trouble. A sheltered spot should,

PLANTS FOR THE WATER EDGE.

EVERYONE who has been on a walking or boating tour along the upper reaches of the Thames—say, for instance, from Wallingford to Lechlade—knows the great beauty of our native water-side flowers. It may be we have passed a spot by the riverside a thousand times without paying any special attention to it, when one day a picture perfect in harmony comes into view. *Rosa arvensis*, with long, overhanging branches almost touching the gently flowing stream, is smothered with pale single Roses; the yellow Flag Iris (*I. Pseudacorus*) is at its best, and around its leaves may be seen the bright blue Water Forget-me-not (*Myosotis palustris*) and the flimsy pink petals of the Ragged Robin, Wild

Under Wytham Woods the meadows are marshy, and here and there occur the Buckbean (*Menyanthes trifoliata*), *Thalictrum flavum*, *Orchis latifolia* and the blue-flowered *Geranium pratense*. Other Thames-side flowers in this neighbourhood are *Epilobium hirsutum*, *E. parviflorum*, the Purple Loosestrife (*Lythrum Salicaria*), *Caltha palustris* or Marsh Marigold, Skull-cap or Hedge Hyssop (*Scutellaria galericulata*), the Water Mint (*Mentha aquatica*), Yellow Loosestrife (*Lysimachia vulgaris*), Money-wort or Creeping Jenny (*L. Nummularia*), Guelder Rose or Water Elder (*Viburnum Opulus*), now showing rich crimson and purple foliage, and shining, half transparent berries; the Flowering Rush (*Butomus umbellatus*) in shallow waters; the Arrow-head (*Sagittaria sagittæfolia*), the Water Plantain (*Alisma Plantago aquatica*), the Water Violet (*Hottonia palustris*) in soft mud banks and submerged in water; that graceful Sedge, *Carex pendula*; the Marsh Horsetail (*Equisetum palustre*) and the Great Horsetail (*E. maximum*), most beautiful relics of a bygone flora; Marsh Helleborine (*Epipactis palustris*), the Grass of Parnassus (*Parnassia palustris*) in marshy places and bogs; the Bitter Cress (*Cardamine amara*), and the Cuckoo Flower or Lady's Smock (*Cardamine pratensis*). The latter, curiously enough, rarely produces seed, but is increased by its leaflets, which are carried about the meadows during flood-time and root in the muddy soil on the sinking of the water. The double-flowered form is not uncommon in the wild state. In the deeper backwaters the Water Lily is common, as is also *Nymphæa lutea*.

Many plants, although not natives, have become naturalised by the side of many streams in England, such as, for example, the Yellow Mimulus (*M. luteus*) and the two Balsams or Touch-me-nots, *Impatiens Noli-metangere* and *I. fulva*. These, like our true natives, the Purple Loosestrife, Willow Herb and Water Forget-me-not, are all quite easily raised from seed, and it is only necessary to plant the seedlings in muddy soil at the water edge, when they will soon establish themselves and spread along

the banks of streams or lakes. Plants like the Royal Fern (*Osmunda regalis*), double-flowered Meadow-sweet (*Spiræa Ulmaria flore pleno*), and Arrow-head (*Sagittaria sagittæfolia flore pleno*) are increased by division of the roots, and they may either be planted now or in March.

Iris sibirica, with lilac purple or bluish flowers, makes a delightful show in early June if planted about the margins of lakes, ponds or streams. When the clumps become overgrown they are easily put right by dividing them up into smaller sections as soon as the flowers fade. *I. lœvigata*, a beautiful Iris of Japan in rich and varied colours, requires special treatment. In Japan it is grown in ricefields, which are heavily manured in winter when dry, and flooded by irrigation in the summer, when the Irises are about 2 inches under water. Here they are best planted in small mounds which are dry in winter and submerged in summer, although at Wisley they are grown most successfully without any special winter treatment. C. Q.

ARUM LILIES FLOWERING BY THE WATERSIDE.

if possible, be chosen, as rough winds are their greatest enemy. They form a succession to those grown in pots, and they may be cut with discretion and used for decorating without spoiling the effect. Unfortunately, their season of flowering is not prolonged such a length of time as those grown and treated with stimulants indoors.

As border plants these form a still longer season of growth and flower, and, where the flowers are wanted, form a useful addition. Stock is easily procurable where a batch of plants are grown inside to try them in this manner, and, as might be imagined, the plants are greatly benefited by a liberal addition of good manure to the soil. Planting may be carried out at the first favourable opportunity after the end of May, and the same applies to those grown in the water. They are very effective when grown in association with Bamboos, Globe-flowers, and last, but not least, *Gunnera manicata*.

Queenstown.

E. B.

Williams or the Meadow Pink (*Lychnis Flos-cuculi*). We see these wild flowers "with a child's first pleasure," as Wordsworth saw the Daffodils by the lakeside.

The Upper Thames, which flows through secluded country, is full of interesting waterside plants, although not remarkable for any very rare species. One of the most interesting is the Snake's-head Lily (*Fritillaria Meleagris*), or Toad's Head, as it is known in Wiltshire. It occurs in damp meadows around Oxford, and again between Colehill and Lechlade, where the river for a short space is bordered with *Ribes nigrum*. *Fritillaria Meleagris* is not the easiest of plants to cultivate. Like British Orchids, some people find them almost impossible. The bulbs may be lifted now, but what is of vital importance is that they should be replanted with out delay, for if allowed to get dry they are apt to lose their vitality. Where it is impossible to plant at once, they should be kept for a few days in sand or fibre.

OUR NATIVE TREES AND THEIR CONGENERS.—III.

By W. BOTTING HEMSLEY, LL.D., F.R.S., V.M.H.

The Birch (*Betula*).—There are two native arboreal species of Birch, though some authors regard them as varieties of one. In addition there is a very dwarf shrubby species, restricted, in this country, to the mountains of Scotland. Birches are now quite confined to the temperate and arctic regions of the Northern Hemisphere, but certain fossil remains of the Australian tertiary strata have been identified as belonging to the genus *Betula*. Between thirty and forty species of this genus have been described, and they girdle the northern temperate and cold zones, forming large forests, especially in Europe and Asia. Upwards of a dozen species are recorded from China, half of these being of comparatively recent discovery. *Betula nana*, the Scottish Mountain Birch, extends into the Arctic regions, but it is not recorded from the extreme limits of flowering plants. Very dwarf tufted Willows and Birches constitute the bulk of Arctic woody vegetation. The so-called Birches of New Zealand are really Beeches, and some further information concerning them will be found under *Fagus*.

The Hazel (*Corylus*).—The Hazel, *Corylus Avellana*, of our woods and hedgerows rarely develops the habit and dimensions of a tree, but it occasionally forms a trunk as much as 3 feet in girth, with a crown 30 feet high. Some of the exotic species are normally trees. *Corylus Colurna*, for example, grows to a height of 60 feet, though this species also is often bushy. *Corylus* comprises eight or ten species, restricted to the north temperate zone and generally dispersed in this region, and most numerous in China. None of the American species reaches so far south as Mexico. *C. Avellana* has a wide distribution in Europe and Asia, and extends to North Africa.

The Hornbeam (*Carpinus*).—The genus *Carpinus* comprises about a score of species, a dozen of which are recorded from China; half of these discovered within the last quarter of a century. *C. Betulus*, the common Hornbeam, is considered to be indigenous in the south-east of England, and it ranges from South Sweden to the south of Europe and West Asia. There are several species in the mountains of North India, and *C. americana* skirts the eastern side of America, from Canada to Florida, reappearing in the mountains of Guatemala. Otherwise the genus is apparently confined to the north temperate

sections or genera: *Fagus* (*Eufagus*), inhabiting the temperate zone of the Northern Hemisphere; and *Nothofagus*, inhabiting the Southern Hemisphere; Chile and Fuegia; New Zealand and Eastern Australia; from Tasmania to Southern Queensland. Most botanists now agree that the Southern Beeches should be

given separate generic rank, though Cheeseman, in his "Manual of the New Zealand Flora," still retains the Southern species under *Fagus*. In this sense the genus comprises about a score of species, a dozen of which are Southern. *Fagus sylvatica*, the common Beech, is considered native in the Midlands and Southern England, but as an introduced tree both in Scotland and Ireland. Closely allied species occur in North America, China and Japan. Some of the Asiatic forms have been described as varieties of *F. sylvatica*. Most of the species inhabiting the Southern Hemisphere

SILVER BIRCHES ON THE OUTSKIRTS OF A FORMAL GARDEN.

The Beech (*Fagus*: *Nothofagus*).—Beeches consist of two

are large, handsome, evergreen trees; some of them constituting extensive forests and yielding valuable timber. Two or three of the New Zealand species attain the height of 100 feet, and *F. Cunninghamii*, one of the chief forest trees of Tasmania, sometimes reaches a height of 200 feet with a girth of 90 feet. Birch is the popular name of these trees in New Zealand, and *F. Cunninghamii* was named Myrtle Tree by the early colonists in Tasmania. Whether we consider the Northern and Southern species as generically different or not, the absence of the type and any close ally from the whole of the intermediate country is a remarkable fact in plant distribution.

The Oak (*Quercus*).—The distribution of the genus *Quercus* is dealt with in the present volume of *THE GARDEN*, page 351. There are two distinct Oaks wild in the United Kingdom, namely, *Quercus pedunculata* and *Q. sessiliflora*, with intermediate forms, supposed to be hybrids or seminal variations. About seventy-five species are on record from China alone, and large areas are still unexplored. Many species are indigenous in the tropical regions of India and Malaya, and one or more descend to the sea-level in Central America and Cuba. *Quercus Robur* is thoroughly naturalised in the Island of St. Helena, where it is common in some localities, grows to a large size, and fruits freely. Some Australian fossil remains have been referred to *Quercus*.

The Elm (*Ulmus*).—Babington, Bentham, Hooker and other writers on the British flora agree in defining two species of Elm, namely the common (*Ulmus campestris*) and the Wych (*U. montana*) with a number of forms or varieties difficult of classification. Several later botanists have made a critical study of the genus *Ulmus*, as represented in our parks and woods, and by experiment have arrived at a knowledge of the true pedigree of some, or all, of the puzzling forms, some of which were known and distinguished by Philip Miller and other writers of his period. In consequence of the confusion in nomenclature, the general distribution of *U. campestris* and *U. montana* is a little uncertain on some points, though both, as ordinarily circumscribed, have a wide area in Temperate Europe and Asia, and also extend to North Africa. Of the genus *Ulmus* nearly a score of species are on record, and they are dispersed almost throughout the north temperate zone. In America there is a southern extension to the mountains of Mexico, where one species occurs. In the Himalayas one species descends into the subtropical districts of Sikkim, and about eight or ten species inhabit China and Japan.

The *Ulmaceæ*, as an independent family, also comprise the genera *Celtis* and *Zelkova*. They are, or have been, regarded by some botanists as a tribe or sub family of the *Urticaceæ*.

THE GARDEN OF LA MORTOLA.

By G. FREDERIC LEES.

Author of "Wanderings on the Italian Riviera," "A Summer in Touraine, &c."

THE fact that the honeymoon of Mr. and Mrs. Maurice Bonham-Carter is being spent on that idyllic little cape which juts into the Mediterranean between Mentone and Ventimiglia once more calls attention to the celebrated garden of exotic plants which the late Sir Joseph Hooker described as being "without a rival amongst the

the finest chapters in the annals of horticulture—lasted for seven years, until March 24, 1875; and how for over thirty years longer Thomas Hanbury continued to plant and sow until the place became that "botanists' paradise" it is to-day.

I have often pictured to myself, when wandering amid the tropical vegetation of La Mortola and along its flowery alleys leading to spots whence you can obtain exquisite views of the rugged Italian Riviera and the turquoise green sea, what the denuded La Mortola must have been like when the two brothers began their work. Imagine them scattering the seeds of *Rhamnus Alaternus*, *Quercus Ilex* and Ivy among the rocks of the valley; planting Roses from their father's garden at Clapham; watching the growth of Passion Flowers, Pæonies and Cedars of Lebanon in the place of grass and weeds; and tending throughout the years the exotic plants—including some eighty varieties of *Acacia*, many kinds of *Cistus*, *Eucalyptus*, *Cupressus*, *Ficus*, *Genista*, *Juniperus*, *Magnolia*, *Melaleuca*, *Yucca* and *Wigandia*—which they had received from the gardens and horticultural establishments of the French Riviera and elsewhere.

Everything that was new, or rare, or curious in the plant world, provided there was a chance of it growing at La Mortola, was obtained. From the *Jardin des Plantes*, at Paris, came several new plants, among them two specimens of an Australian Palm, *Livistona australis*, and one of the large Chilean Palm, *Jubæa spectabilis*, which are still in the garden. The little *Erigeron mucronatus*, now half wild, not only at La Mortola, but also at many places in the neighbourhood, came from Professor Planchon of Montpellier; and from Sahuts' nursery garden at the same

ALOES AND THE BOLE OF A GIGANTIC BLUE GUM TREE (*EUCALYPTUS GLOBULUS*) AT LA MORTOLA.

principal collections of living plants in the world." Many of my readers have certainly already heard of La Mortola and some, perhaps, have visited it, but one cannot tell too often—at any rate in outline—the romantic story of how Thomas Hanbury, in 1867, when in his thirty-fifth year and fresh from the East, where he had acquired a large fortune, discovered the little peninsula named after the Myrtle and purchased it, with an ancient Italian country house, the Palazzo Orengo; how he set to work, in collaboration with his favourite brother, Daniel Hanbury, an eminent botanist and pharmacologist, to accomplish that dream of his youth "to make a garden in a southern clime, and to share its pleasures and botanical interests" with that brother; how that beautiful collaboration—truly one of

place arrived many interesting forms of Citrus, including the Bergamot. Daniel Hanbury possessed a very wide circle of botanical friends, so that he was able to obtain rare and valuable plants from all parts of the world. He devoted special attention to obtaining those of economic and, especially, pharmaceutical importance.

Thus, year after year, the two brothers sowed and planted. As early as June, 1868, forty different species of succulents are mentioned in their note-books; and in the autumn of the same year the collection had doubled, thanks to specimens from Kew, Paris, and an old friend at Reigate, the late William Saunders. Most of the large Agaves and Opuntias, now such a striking feature of La Mortola, date from the very first years of that brotherly and touching collaboration.

To mention but a tenth part of the plants and trees which appeal to the botanist and garden-lover is impossible in the limited space at my disposal; all that I can attempt to do is to give the following brief notes on certain striking species.

Most of the Acacias grow well. One that is particularly noteworthy is the Mexican *A. sphærocephala*, which provides an example of that myrmecophily which Belt first pointed out in his "Naturalist in Nicaragua." The long needles of the plant are inhabited by ants, which obtain food and drink from the leaves of the plant, which they defend against herbivorous insects.

Agaves are quite at home and attain their full growth. The largest are *A. salmiana* and *A. atrovirens*, much cultivated in Mexico for pulque. Next in size comes *A. Franzosinii*, which the late Professor J. G. Baker of Kew called "The Prince of the Agaves" on account of its beautiful greyish white or bluish leaves. The smallest of the Agaves is *A. pumila*, which never grows taller than 2 centimètres to 3 centimètres.

Aloes thrive equally well, and have become so well acclimatised that they have adapted their flowering season to the Riviera latitude. The most beautiful species, which flower in South Africa during June and July, bloom at La Mortola from Christmas until spring.

The Argan Tree of Morocco was grown from seed received from Daniel Hanbury in 1870, and is interesting because a kind of oil is made from its fruit. At La Mortola it is a thorny shrub, with fruit the size of an Olive.

Among the most beautiful plants in the garden are the Buddleias, especially *B. madagascariensis*, a huge climber covered in spring with hundreds of long, fine yellow racemes. *Casimiroa edulis* is represented by two fine trees, 9 mètres high. In October it produces a good crop of fruit, which the late curator, Herr Alwin Berger, told me is delicious when eaten at once, but becomes very bitter after a few days.

The collection of Agrumi is one of the most complete in the world. There are even a few small specimens of the form *Bizzaria*, which Risso called "the most singular and curious tree in the whole of the vegetable kingdom," since it produces fruit bearing the characters of Oranges, Lemons and Limes. The form *Citrus japonica*, known as "Buddha's Fingers," owing to the carpels at the top of the fruit being like the fingers of a hand, is also there.

There were once fifty different species of *Eucalyptus* at La Mortola, but Thomas Hanbury reduced the number, as they took up too much

room. The largest of these trees—it is now so gigantic a specimen that I could photograph only a portion of it—is a specimen of *E. globulus*, which measures 5·5 mètres at its base and has a height of 24·5 mètres. When planted in the spring of 1869 it was 90 centimètres high. From this fact alone it may be judged what a change has come over the vegetation of La Mortola since the bare forest land of the little cape was taken over forty-eight years ago.

ROSE MME. ALFRED CARRIERE.

This is one of the most beautiful of summer and autumn flowering Roses. It is not a novelty, but it is welcome everywhere, on pergola, and in both town and country gardens. It seems

ROSE MME. ALFRED CARRIERE IN A SURREY GARDEN.

indifferent to its surroundings, and the large double flowers, as shown by the photograph sent by Mr. C. Martineau of Esher, and taken in the garden of Mr. J. Thorneby in the same village, are produced in great profusion. As a writer says: "Late in the summer and throughout the autumn many are the Roses that may be cut long stalked for free arrangement in water; but early in June there is only this one good Rose that can be so used." Mme. Alfred Carrière, classed as a Hybrid Noisette, has large, pale leaves of the Tea Rose character and large, loose flowers of a low-toned warm white, capital to gather into a loose bunch in the hand and put straight in water without elaborate arrangement. It grows and blooms early, and is a Rose of much grace and beauty. In the National Rose Society's official catalogue it is described as the best white, hardy climber.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Carnation Malcolm.—A Perpetual-flowering sort of large size and rosy scarlet colouring. Shown by the Misses Price and Fyfe, Birchgrove, East Grinstead.

Chrysanthemum James Fraser.—An exhibition Japanese of the largest size and great depth. The colour is best described as brassy yellow, which, with the long drooping petals, renders it most distinct.

Chrysanthemum Flossy.—The largest pure white single we have seen, the colour being exceedingly pure and good. It should be most useful in decoration. These were from Messrs. W. Wells, Limited, Merstham.

Odontioda Aphrodite.—A remarkable hybrid novelty, the purplish, mauve-shaded sepals and petals freely freckled with white being in fine contrast to the golden-crested lip. Shown by Messrs. Charlesworth and Co., Hayward's Heath.

Lælio-Cattleya St. Alban (L.-C. Golden Glory × *Cattleya dowiana aurea*).—A very beautiful and distinct novelty. Sepals and petals old gold to palest orange, the frilled lip of rich red orange, deepening at the tube, where it is heavily lined. From Messrs. Sander and Sons, St. Albans.

Lælio-Cattleya Invincible var. His Majesty (L.-C. dominiana × L.-C. blechleyense).—The sepals are of purplish hue, the handsome lip of rich crimson. From Messrs. Sander and Sons, St. Albans.

SEEDLING COMMENDATION CARD.

Odontioda Armstrongæ (O. Bradshawæ × *Odontoglossum Armstrongæ*).—A very beautiful

variety of reddish chestnut tone, freely reticulated white, the rich mauve coloured lip rendering it very distinct. From Messrs. Armstrong and Brown, Tunbridge Wells.

The foregoing novelties were before the Royal Horticultural Society on December 7, when the awards were made.

A SELECTION OF CHRYSANTHEMUMS.

NEARLY every cultivator grows more varieties than is desirable each year. Those who have had much experience reduce the number as much as possible; but as new varieties are placed on the lists every year, some of these must be tried. Many amateurs have not the necessary space to devote to new sorts, and so they and beginners depend to a great extent on the results of trials made by others who possess plenty of space, both outside and inside the houses. The following list will prove helpful to many readers. The varieties named have done remarkably well during the past season, and may be relied on by amateur cultivators.

Twenty-Four Japanese for Exhibition.—

Mrs. James Gibson, mauve pink, natural break, first crown bud, 4 feet high; Queen Mary, white, should be stopped early in April, first crown, 4 feet; Miss A. E. Roope, 4 feet 6 inches, stop plants third week in March, first crown—this is the finest yellow; Francis Jolliffe, creamy yellow, petals edged light rose, natural break, first crown, 5 feet; Mrs. Gilbert Drabble, pure white, stop plants the third week in April, first crown, 4 feet; Bob Pulling, yellow, natural break, first crown, 3 feet 6 inches; Rosamund, primrose, suffused old rose, 4 feet; F. S. Vallis, pale yellow, natural break, first crown, 5 feet; Amy Poulton, flesh pink, stop first week in April, first crown, 3 feet 6 inches; Lady Talbot, straw yellow, stop early in May, first crown about August 10, then a deep, fine bloom may be expected; Dandy, old rose, amber reverse, stop March 20, second crown, 4 feet; Mr. Keith Luxford, white, slightly shaded green, natural break, first crown, 4 feet 6 inches; His Majesty, velvety crimson, natural first break, 3 feet 6 inches; H. E. Converse, reddish bronze, gold reverse, natural break, first crown, 4 feet; Pockett's Crimson, a deep, rich crimson, stop first week in May, 3 feet—if the natural break occurs about that date, first crown buds will be available at the right time in August; William Turner, pure white, stop late in May if natural break does not occur then, 4 feet; Mrs. R. C. Pulling, light yellow, stop early in April, first crown, 4 feet; Mrs. R. Luxford, Indian red, natural break, late first crown, 3 feet; Master James, chestnut red, natural break, first crown, 3 feet; Marie Loomes, chestnut terra-cotta, natural break, first crown, 4 feet; Fred Chandler, red, gold reverse, stop late in March, first crown, 3 feet 6 inches; Miss Elsie Davis, rosy mauve, natural break, first crown, 3 feet 6 inches; Mrs. Edgar A. Tickle, mauve pink, natural break, first crown, 4 feet; and Kara Dow, bronze, gold reverse, natural break, first crown, 4 feet. It should be distinctly understood that the foregoing are Japanese varieties for exhibition purposes. Selections of other types will be given later.

AVON.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Cucumbers.—A sowing of Cucumbers may be made now to replace the plants which are supplying fruits during the winter months. Sow the seeds singly in 3-inch pots and plunge the pots in a hot-bed. The bed should be quite near the glass, so that the seedlings may have the benefit of its warmth till they have made some progress. When the young plants are fairly well rooted, transfer them into 6-inch pots, using a compost of two-thirds fibrous loam and one-third leaf-soil. In the meantime a hot-bed must be prepared in a light structure, on which to grow the plants. When ready, plant them in mounds of loam and leaf-soil about 5 feet apart. A temperature of 65° or 70° must be maintained, and during times of severe frost a covering should be placed over the glass at night to conserve the heat. The old plants may be encouraged to mature their fruits for some time to come by careful attention to the regulation of young growth, watering, and the maintenance of an equable temperature.

Late Grapes.—All late Grapes should have been cut by this date, so that the Vines may have their necessary rest. The borders will be in need of a thorough soaking of water, and if they are in a clean, healthy condition, a good soaking of diluted farmyard drainings will be of great benefit. If the borders need attention in regard to renovating or extending, this work should be done at once. The pruning of all Vines must be completed without delay.

Plants Under Glass.

Mignonette.—The plants raised in the autumn may be shifted into 5-inch pots when ready, using a compost of loam, leaf-soil and brick rubble. A shelf near the glass in a cool house will suit them till they commence to flower. They will now require the support of neat stakes.

Cyclamen.—The young plants which were raised from seed in September are now ready for a shift into 2½-inch pots. A compost of loam, leaf-soil and sand will suit them. When potted, stand them on a shelf near the glass in a house having a temperature of 60° or 65°. The pots should, if possible, be stood on a moist base or plunged in boxes of fibre. Spray them two or three times a day with lukewarm rain water. Old plants which are flowering must be given plenty of stimulants.

The Flower Garden.

Newly Planted Roses.—In the event of a severe spell of frost, no time should be lost in protecting Roses which have been recently planted. Strong winds will often cause newly planted Roses to become loose in the ground, in which case they must be made firm by pressing the soil about the roots with the foot. Briar stocks may be planted at any time now when the weather is open. As a rule, suitable Briars may be found in the neighbourhood for this purpose. Roses and Brambles which have been planted in the woodland need pruning or thinning annually. In some cases it may be necessary to cut them down to the ground.

Carnations.—Should there be danger of the plants being damaged by game, the beds must be protected by placing wire netting around them. Frequent light dustings of soot will also help to keep game off. Examine the plants after severe frost, and press the soil about them where it has become loose. A handful of coal ashes placed around the collar of each plant is an excellent protection, should the weather be unusually severe.

Box Edgings.—The planting of Box edgings may be carried out at any time now when the weather is open. Gaps may also be filled up where these have occurred. Cuttings for this purpose may be taken from the common Tree Box, but they must be obtained from plants in exposed situations.

The Hardy Fruit Garden.

Renovating Old Orchard Trees.—An effort should be made to keep old orchard trees in a good fruit-bearing condition, especially valuable varieties.

One of the chief causes of a general weakening of the trees is neglect in pruning or thinning the branches annually. It is not uncommon to see trees growing in orchards literally choked with weak, useless growth. A judicious annual thinning of such trees would quickly bring them back to a healthy, fruit-bearing condition. Valuable old trees should also receive assistance in the matter of feeding. At this time of year there is always a plentiful supply of liquid manure in the farmyards, which should, if possible, be carried to the trees. Artificial manure will also be beneficial, but this should be scattered over the roots during wet weather so that the rains may wash it down.

The Kitchen Garden.

Early Peas.—A sowing of Peas may be made outdoors on a warm border when the ground is in suitable condition. The seeds should be sown in shallow trenches, and if the ground is on the wet side, a little dry soil from the potting-shed may be scattered along the trenches previous to sowing the seed. The variety Pilot is excellent for this sowing. Mice must be watched for till the seedlings are through the soil. Traps should be kept constantly set along the rows for these pests.

French Beans.—A sowing of a dwarf variety, such as Osborne's Forcing, may be made now in 7-inch pots. A good substantial compost must be used, and room should be left for a top-dressing of soil when the plants are setting their pods. A position quite near the glass must be given them, and a temperature of 60° or 65° maintained.

Onions.—For producing large bulbs, a sowing may now be made either in shallow boxes or 3½-inch pots. Sow the seeds thinly, so that the seedlings may receive little damage to the roots when transplanted to other boxes or pots. A compost of loam, leaf-mould and manure from the Mushroom-house will be found suitable. Place them on a shelf in a Peach-house which has just been started.

Cauliflowers.—The plants in cold frames must be given abundance of air whenever possible. Keep a careful watch for slugs. They may be kept off by scattering lime around the sides of the frame. Keep dead leaves removed, and where the plants are planted out, the soil must be moved occasionally with a pointed stick.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Broccoli.—During very severe weather it will be much safer to run no risks, but to protect the plants with a light covering of clean straw or Bracken. Upon the return of mild or wet weather it should be at once removed.

Parsley, although fairly hardy, should be protected if good clean leaves are to be obtained conveniently to supply demands. Either frames or other glass protection can be used, and where the plants have already been well stripped, some can be lifted and brought indoors where there is a certain amount of warmth—just enough to encourage a firm growth.

Potatoes.—Tubers started in heat at the present time will produce a fair crop in March if they are given correct treatment. Ten-inch pots should be used, half filled with loam and leaf-soil. The soil must be light, and yet rich enough to nourish the crop. The pots should be placed in an early vinery or Peach-house near the pipes, but in a position where they are close to the glass, so that the growth may be sturdy. May Queen is a splendid variety to grow in this way.

Peas.—Where one has plenty of accommodation for early vegetables indoors, a few pots of early Peas may now be sown. Being grown so early and during the very short days, they must not be expected to produce anything like an outdoor crop. A dwarf variety, such as American Wonder or Daisy, should be grown.

The Flower Garden.

Bulbs in Grass.—Early patches of Snowdrops will soon be appearing through the surface, and

no time should now be lost in giving the final brushing of any grass where they are situated.

The Rock Garden.—Additions or alterations should be carried out, if possible, before growth becomes active of any of the early subjects. This could proceed in mild weather, but should not be attempted while there is any trace of frost remaining in the ground. Some of the very free growing plants which have taken possession of more than their fair share of space ought to be lifted and replanted after having been reduced to reasonable proportions. Examine any plants which are of doubtful hardiness, and attend to protection if it is necessary.

Plants Under Glass.

Schizanthuses.—Plants raised from seed sown during autumn will in most cases require pinching if a bushy habit is to be obtained. The final potting must soon be done, also staking attended to. Continue to grow fairly cool, but avoid admitting air recklessly during cold weather. If fly is troublesome, fumigate the house with a nicotine compound.

Begonia Gloire de Lorraine.—As plants become shabby and pass out of bloom, they should have all flowering shoots removed and be partly cut back. If they are then kept a little drier than previously, they will benefit from the rest and are certain to break into growth with much greater vigour when required to produce cuttings.

Amaryllids.—These produce their flower-spikes very quickly if the plants have already had a good rest. Only good bulbs which are known to contain embryo flowers should be selected, and before putting them in heat they can have a little of the surface soil removed and be given a top-dressing which should contain a certain amount of some concentrated fertiliser.

Chrysanthemums.—As the single-stemmed plants pass out of bloom their places can be taken by the later decorative varieties. Plants after having been cut over should not be relegated to some out-of-the-way position in almost entire shade, otherwise the cuttings produced for future stock will be of poor quality. Plants being kept for producing cuttings should receive equally as much attention as those in flower.

Pot Roses.—A start can be made by bringing a few plants indoors if very early Rose buds are desired. Too much heat at the commencement would produce weak growths. The drainage should be examined at the same time as the pots are being washed. Only a very slight pruning should be given if it is at all necessary.

Fruit Under Glass.

Early Melons.—If the grower has plenty of heat at command right through the winter, a few seeds may now be sown. Where sufficient heat cannot be depended upon, it is more profitable to wait until early in January, as by sowing now in genial conditions ripe fruit can only be had from this sowing at the earliest a few days in advance. Sow in 2-inch pots in loam which has already been heated to the temperature of the house. Mice quickly discover and devour Melon seeds, so that precautions must be taken. As soon as germination has taken place, stand the plants on a shelf near the glass to encourage a sturdy growth, and see that a minimum temperature of 65° is maintained.

The Hardy Fruit Garden.

Spraying Fruit Trees.—This may be dealt with during mild weather when there is an absence of wind. If a proper spraying machine is used for making a fine spray, there is naturally less waste of material than when an ordinary syringe is used. The caustic alkali washes should not be used every season, as the bark becomes injured by too frequent a use of them. Every second or third year is frequent enough to remove lichen and general parasites. Where fruit trees are growing in vegetable quarters, care must be taken that the spray is kept off the vegetables.

Grafting.—Where any of this work is contemplated, the prunings of the varieties to be used should be preserved, properly labelled, and heeled in in some sheltered border where they will remain in good condition until required in spring.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

BORDER CHRYSANTHEMUMS (R. M.).—The following varieties are of first-class merit: Goacher's Crimson, bright crimson, 2½ feet; Aquitaine; Normandie; Ethel Blades, chestnut scarlet, 3 feet; Dolores, terra-cotta, 2½ feet; Cranford Pink, a clear pink, 2½ feet; Cranford Yellow, 2½ feet; Chaldon, reddish crimson, very suitable grown as single plants, 2½ feet; Belle Mauve, mauve, a beauty, dwarf, 2 feet; Patricia, mauve pink, 2 feet; Provence, pink, gold tips of petals, gold centre, 2½ feet; Roi des Blancs, white, 2½ feet; Perle Rose, pink and rose, 2 feet; and Mrs. E. V. Freeman, deep crimson, 2½ feet to 3 feet. Notes on good varieties for pot culture and exhibition will appear in due course.

ROCK GARDEN.

WANTED: RABBIT-PROOF ROCK PLANTS (Mordington).—It is difficult to say which rock plants would be proof against rabbits, but it is likely that all the Sedums and Sempervivums would escape injury, probably also Campanulas and Saxifrages. The best plan, however, would be to protect your rock garden with wire netting; then you could grow whatever you wished. It is not necessary to give Grape Muscat of Alexandria sulphate of iron in order to make it colour. As a rule it requires a little more sun and a little higher temperature than most Grapes in order to finish it well.

ROSE GARDEN.

BEST ARTIFICIAL MANURE FOR ROSES (Maida Vale).—It is presumed that your Roses have not been planted this autumn, and can therefore be looked upon as established. In that event, the safest of the three artificial manures mentioned by you to be used as an all-round fertiliser is undoubtedly the mixture known as Tonk's Manure. It can be obtained ready made in small or large quantities from most horticultural sundriesmen, and should be applied after the pruning is completed, and watered in as directed. If, on the other hand, your trees have only been recently planted, avoid all artificial manures during 1916 as you would poison.

FRUIT GARDEN.

FIGS NOT RIPENING (W. H.).—When forced under glass the Fig is one of the most fruitful trees we have, always bearing two distinct crops of fruit, and sometimes three crops, every year. The first crop is always borne on the old wood of the previous year's growth, the second crop on the shoots of the current year's growth, and the third crop (which is of little consequence) from the lateral shoots which issue from the shoots of the current year's growth. Now, in the case of outdoor Figs, it is only the first crop (that which grows on the old shoots of the previous year's growth) which we can ripen in this country. That which the current year's growth produces scarcely ever ripens, and we suspect that is the cause of the fruit not ripening in your case. If you can send us a shoot with the fruit on, we can tell you. The way to encourage your trees to bear on the old wood is by thinning out the branches freely, so that sunshine and light can play freely among them in summer, and so ripen the wood and prepare the shoots to bear.

AMERICAN BLIGHT (M. Badger).—American blight is one of the most troublesome pests, and not easy to get rid of unless constant attention is paid to it. Where a number of trees are attacked, it would probably pay to purchase an injector and inject carbon bisulphide at the rate of 2oz. to a tree in four places near the roots, for at times the pest lives on the roots as well as on the shoots. This must be combined with spraying. Caustic soda, 2lb., dissolved in water, 10 gallons, is one of the best spray materials to use, but it must be forcibly applied. The ordinary mist-like spray usually applied is quite useless for the purpose of combating this pest. Paraffin emulsion used in the same way is also good. In summer, every spot affected should be painted with methylated spirit; or a mixture of 4oz. of carbolic soft soap with a gallon of water, and a wineglassful of paraffin stirred in, may be used. A stiff brush is best with which to rub the stuff well into the cavities.

TRAINING CORDON PEACH TREES (Tim).—Peach trees succeed very well on their own roots, but they succeed better when worked on the Plum stock. The training of a cordon Peach tree is a very simple and easy matter. You say of your seedlings that some have one stem, some have two, and some more. If we treat of a single cordon it will be enough, as the same treatment repeated will answer for double or treble cordons. The first thing to do with your young seedlings is to cut each stem down to within 9 inches of the ground. Next spring you will find that buds will break all over the stem of the cut-back shoot. Select the terminal bud to form the leading main upright shoot of next year. This must be allowed to grow its full length without interruption. The remaining buds on the stem should be treated as follows. Reduce them to three (at even distances apart) on one side, and two on the other. These side buds in due time will develop into shoots. As soon as this is the case, and when five leaves have been developed, these young shoots must be stopped (meaning the pinching off with the finger and thumb of the centre of the shoot). In consequence of this stopping, other small shoots will issue from the stopped shoots. These are termed sublaterals, each of which must be stopped at the third leaf. Any subsequent growth

which may proceed from the latter should be stopped in the same way. The centre shoot should be staked or nailed to the wall for support as growth takes place. This finishes the process of training for the first year. Second year.—Cut back the main shoot to within 12 inches of its base. The side shoots below should also be pruned back, the stronger of them to within 3 inches of their base, and those not so strong to within two buds of their base. There will, no doubt, be some flowers on these side shoots, and in due time possibly fruit also. Do not let a tree bear more than two fruits the first year. The same process of pruning will have to be continued each succeeding year until the cordon has attained to the height desired. After that, all shoots will have to be spurred back to within three or two buds of their base, as described above. It is generally the case with young Peach trees that two or three years after planting they develop some gross, sappy shoots which cannot be properly ripened, and therefore prove infertile. Indeed, if such growth is not arrested, in time it will prove to be the ruin of the tree. Therefore, as soon as indications of this sort are noticed, take up the trees in autumn, as soon as the leaves have fallen, cut back the strong roots by half their length, and slightly shorten all the smaller roots as well. This will cause an enormous multiplication of new, small, fibrous surface roots, which will react on the branches, compelling them to be of moderate growth and productive of fruit. The Peach is a tender tree, and sometimes its branches are injured by hard frost during winter; therefore it is advisable to defer its pruning until the middle of February.

MISCELLANEOUS.

NAMES OF FRUIT.—*Pitchford.*—1, Grosse Calebasse; 2, Duchesse de Bordeaux; 3, Thompson's; 4, Maréchal de la Cour; 5, Boston Russet; 6, Royal Nonsuch; 7, Cat's Head.—*F. G., Hays.*—1, Mère du Ménage; 2, Allington Pippin; 3, Emperor Alexander; 4, John Apple; 5, Newton Wonder.—*New Castle.*—Emperor Alexander.—*J. R., Holmwood.*—Apple Newton Wonder.—*Bristolian.*—1, Flanders Pippin; 2, Rambour Franc; 3, Rival (?); 4, Bess Pool.

NAMES OF PLANTS.—*Fish.*—Ferns, Aspidium angulare (woolly), Nephrodium dilatatum (branching), Arenaria peplodes (small white flowers).—*A. L. N.*—1, Cannot identify without flowers—probably Calanthe; 2, Buddleia species; 3, Selaginella kraussiana; 4, Helxine Solierii; 5, Ophiopogon japonicus; 6, Acer palmatum.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

THE fortnightly meeting held on December 7, the last for the present year, though below the average of such meetings, was not without interest or variety. Chrysanthemums from Merstham were of an imposing order, while Carnations from Hayward's Heath were presented in most artistic style. For the rest there were bright colour patches of Begonias and interesting exhibits of Fern variations from Edmonton, a fresh-looking group of berried and other shrubs from Richmond, and delightful exhibits of Orchids from a variety of sources. There were no exhibits of fruit or vegetables.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. W. G. Baker, A. Turner, C. E. Shea, W. J. Bean, J. Green, R. C. Notcutt, G. Reuthe, C. B. Fielder, J. W. Moorman, W. Howe, T. Stevenson, W. Bain, J. Dickson, C. Dixon, J. T. Bennett-Poë, C. E. Pearson, J. Hudson, J. W. Barr, E. H. Jenkins and W. P. Thomson.

Messrs. Piper, Bayswater and Barnes, again contributed a very extensive exhibit of choice shrubs, coniferous plants and climbers, not a few of these being of high ornament. Of this type were Berberis Wilsonae (full of rich scarlet berries), the Pernettys (in rose, white and scarlet), Cotoneaster humifusa, Skimmias and others. Giant examples of Retinospora obtusa nana were very fine. Trochodendron aralioides is most distinct in leaf and branch; Berberis japonica intermedia and B. j. Bealii, both yellow flowered, are welcome at this time for leaf beauty, flower and fragrance; while Juniperus tamariscifolia aurea and Cryptomeria japonica elegans, the last now in bronzy garb, afford a colour beauty by no means common at this season.

Mr. L. R. Russell, Richmond, contributed berried and other shrubs and climbers extensively, such as Aucuba japonica vera, Crataegus Pyracantha and C. P. Lelandii (rich scarlet and orange scarlet fruited respectively) being most effective. Cotoneaster angustifolia, with yellowish, bird-proof fruits, was also good. Other interesting plants included Hedera Helix digitata aurea (now in bronzy attire), H. H. dentata variegata, Euonymus in variety and Eurya latifolia variegata.

Mr. G. Reuthe, Keston, Kent, had a considerable display of Norines. Prince of Orange, Plantii (rich scarlet), coruscans major, flexuosa alba, Mrs. Willoughby (salmon and white), Henry Merritt (pale salmon), India (of Fairmount Carnation colour), and Romance, which is in the same colour range as the last, were included. A few choice alpinas and handsome examples of Christmas Roses were also on view.

Mr. George West, The Nurseries, Datchet, set up a lovely group of the new Carnation Nora West, of lovely deep salmon tone and remarkably free flowering. It is stated to be a seedling from Winsor, and is possessed of the same free-flowering qualities.

Messrs. W. Cutbush and Sons, Highgate, N., exhibited a capital group of Carnations, of which White Wonder,

Sunstar (yellow), Lady Ingestre (salmon), Champion (the finest scarlet), R. F. Felton (pink), White Swan, Scarlet Carola, May Day and Carola (crimson) were very fine. *Solanum aculeatissimum* (ciliatum) in fruit in pots was also well staged amid ferns and small Heaths.

The Misses Price and Pyfe, Birchgrove, Sussex, set up a nice group of single and decorative Chrysanthemums and Carnations. Marion, deep pink of a very beautiful shade, is a self-coloured flower that should light up well. It is very effective in the mass. Rosy Amaranth, Mrs. Andrew Walker (bronze) and Bronze Cheer were other good Chrysanthemums. Of Carnations, Malcolm (rosy scarlet), Ian (clear pink), Snowstorm, with Jean and Alison (both of good pink) were also of note.

Messrs. H. B. May and Sons, Edmonton, displayed winter-flowering Begonias in groups, such as Mrs. Leopold de Rothschild, Masterpiece and Glory of Cincinnati (all of the Gloire de Lorraine set), with Winter Cheer (red), Optima (palest orange) and Exquisite (salmon and rose) of the tuberous-rooted section, all being well shown. Cyclamen, too, were very good, while a few of the crested and crispum *Scolopendrium*s were very beautiful. Of these, grandiceps and grande were among the most striking. A complete set of fronds of the variations of the common Polypody, *Polypodium vulgare*, were of much interest. Some twenty-six varieties were so staged, the most comprehensive collection we remember to have seen.

Messrs. Stuart Low and Co., Enfield, staged a very fine lot of Carnations in amply filled stands and vases. Some of the best were Pink Sensation, Alice (a novelty of merit), Mrs. Mackay Edgar (pink), Gorgious (the best cerise), Purple Robe, Satin Robe, Countess of Pembroke (cherry red), Matchless (fine pure white, large and handsome), White Enchantress, and Enchantress Supreme (one of the finest pink Carnations extant).

Messrs. Allwood Brothers, Hayward's Heath, arranged with much skill and effect a capital lot of Carnations fronting a mirror background, the arrangement reflecting the use and beauty of the flowers in a two-fold degree. Artistic and good in itself, and getting away from the stereotyped way of showing these flowers, the exhibit, while of educational value, also demonstrated originality of thought and the possibilities of the flower when required on a lavish scale. Vases, stands and pendent baskets were freely employed. Mary Allwood, Cardinal (pink), Wivelsfield White, Mrs. B. P. Cheney (scarlet and white fancy), Rosalind, Niobe (salmon), Carola, Triumph and Mrs. C. W. Ward were among the varieties used in this imposing lot. A groundwork of velvet and garnishings of Asparagus and Smilax also lent their aid.

The Misses Hopkins, Shepperton-on-Thames, again showed a small collection of alpine and allied plants in boxes.

Messrs. W. Wells, Limited, Merstham, arranged a table of superbly grown exhibition and decorative Chrysanthemums, the imposing display constituting a feature of the exhibition. Crimson Velvet, Bronze Beauty, Lady Mowberry (yellow) and Flossy (purest white—award of merit) are singles of high rank. Louisa Pickett is a giant exhibition Japanese; James Fraser, golden Japanese; while W. Rigby is of pale yellow tone and a sport from Mr. G. Drabble. Some of these giants were nearly a foot across.

ORCHID COMMITTEE.

Present: J. G. Fowler, Esq. (chairman), Sir Jeremiah Colman, Sir Harry J. Veitch, and Messrs. J. O'Brien, Gurney Wilson, W. Bolton, J. Wilson Potter, F. J. Hanbury, Pantia Ralli, T. Armstrong, A. McBean, W. Cobb, J. Charlesworth, J. E. Shill, C. H. Curtis, W. P. Bound, A. Dye, S. W. Flory and R. B. White.

Messrs. Armstrong and Brown, Tunbridge Wells, exhibited some exquisitely beautiful Orchid hybrids, of which *Odontioda Armstrongæ* (O. Bradshawæ × *Odontoglossum Armstrongæ*) received a seedling commendation card. The sepals are of reddish chestnut tone, reticulated white, and with deep mauve-coloured lip. *Odontoglossum Philo* (O. excellens × O. eximium) was also very fine, and there were half a dozen other seedlings of merit and distinction which we shall doubtless see again.

Messrs. Flory and Black, Slough, had a variety of *Cymbidiums* and others useful at this season.

Messrs. Hassall and Co., Southgate, showed *Cypripedium*s well, such as *Thalia*, Mrs. Francis Wellesley, *lecanium stoffordianum*, I. Carona and *Priam* being noted. *Cattleya Sylvia* and *C. alba perfecta* Miss Williams were other important items.

Messrs. J. and A. McBean, Cooksbridge, had well-flowered examples of *Odontoglossum Charlesworthii*, with *Cymbidium Doris* and a variety of *Cypripedium*s. Mr. Harry Dixon, Wandsworth Common, displayed *Odontoglossum armainvillierense* *Xanthotes*, *Cattleya labiata alba*, and *Oncidium cheirophylla* freely.

From Messrs. Charlesworth and Co., Hayward's Heath, came a highly attractive grouping of *Laelias*, a centre being formed of the richly coloured *L. gouldeana*, flanked at right and left by *L. autumnalis* and *L. anceps* in considerable quantity. *Cattleya o'brieniana* *alba*, *Laelio-Cattleya Golden Oriel*, *Odontoglossum*s in charming array and variety, with *Cypripedium*s, were all in force. The new *Odontioda Aphrodite* (see "New and Rare Plants," page 617) was also in this group. It is of much merit and distinction. The grouping was most effectively done.

Mr. C. F. Waters, Balcombe, Sussex, had a small collection of well-blotched *Odontoglossum*s, with *Cypripedium*s and others.

Messrs. Stuart Low and Co., Jarvisbrook, Sussex, contributed *Laelio-Cattleya luminosa* (bronze sepals and rich crimson lip), *Odontioda Cooksona*, O. *devosiana*, *Cattleya Raphaelæ* *alba*, *Brasso-Cattleya Imperatrice* de Russie and *Oncidium varicosum* among many others.

PERPETUAL-FLOWERING CARNATION SOCIETY.

The winter exhibition—the nineteenth held under the auspices of the society—was held at the Royal Horticultural Hall, Vincent Square, on December 8. From the standpoints of extent and competitive zest—particularly in the more important classes—it was one of the smallest yet held. For example, no exhibit was staged in Class 1 (for the Monro Challenge Cup), hitherto a leading feature of the show, and in which only the largest growers could compete with any possible hope of success, a like thing happening in the Brunton Challenge Cup Class, which was for three vases, twelve blooms each, of British novelties. These in the past, while adding weight and prestige to the show as a whole, have contributed not a little interest, together with the important object-lesson of high cultivation and the incentive to produce novelties at home, which is their respective aims. For the American Cup only one competitor staged. The gardeners' classes were generally strongly contested, and good flowers shown. Only one novelty, Mrs. Mackay Edgar (from Messrs. Stuart Low and Co.) received an award of merit. Following are the more important exhibits.

SECTION A (OPEN).

Messrs. W. Wells, Limited, Merstham, were the only exhibitors of three vases of twelve blooms each of American novelties distributed since January, 1912, for which the American Carnation Society offered a challenge cup. The varieties were Laura Webber (pink), Pink Sensation and Champion (scarlet), an excellent trio, well grown and staged.

COLOUR CLASSES.

Twenty-five blooms of any one variety, Enchantress, Lady Meyer, R. F. Felton or like shade. The latter was staged by Mr. G. Lloyd Wigg, Rockshaw, Merstham, who took first prize with excellent blooms; second, Messrs. W. Wade and Sons, Parsons Drive, Wisbech; third, Mr. J. C. Jenner, Rayleigh, both showing Enchantress.

Twenty-five blooms of Baroness de Brien, Pink Delight or like colour: First, Messrs. W. Wells, Limited, with Lord Kitchener, a lovely shade of salmon pink; second, Colonel F. C. W. Rideout, Clury Carnation Nurseries, Langley, with Baroness de Brien; third, Mr. H. T. Mason, Hampton Hill, who staged Enchantress Supreme.

In the rose pink class for a like number, Messrs. W. Wells, Limited, led with an excellent lot of Pink Sensation, Mr. J. C. Jenner taking second prize with Rose Pink Enchantress.

In the Lawson and Mrs. C. W. Ward class (cerise shades), Colonel F. C. W. Rideout took the lead with the last named variety, Mr. H. T. Mason, Hampton Hill, having a capital vase of Rosette in the second place. Only two entered.

For a like number of any one white-flowered variety, three entered, Mr. J. C. Jenner, Rayleigh, having a superb vase of White Enchantress in the first place, Messrs. Wade and Sons, Wisbech, and Mr. H. T. Mason, Hampton Hill, both staging White Wonder and taking second and third prizes respectively.

Three competitors also staged in the scarlet-flowered class, Messrs. W. Wells, Limited, Merstham, who gained first prize, showing a very even lot of Aviator in the pink of condition. The flower is of medium size and of intense deep scarlet. Mr. H. T. Mason, Hampton Hill, took second with Scarlet Glow, a more brilliant scarlet and larger. The flowers are flatter, however, and two or three had passed middle age. Mr. J. C. Jenner was third with Champion.

Twenty-five blooms, crimson or like shade: Mr. H. T. Mason, Hampton Hill, led the way with his crimson seedling, Warrior, a variety of much merit and distinction. Mr. J. C. Jenner and Messrs. Wade and Sons staged Triumph, and were second and third respectively.

For twenty-five blooms in the fancy Carnation class, Major Sir Randolph Baker, Bart., Blandford, took the leading place with Sunstar, yellow, lightly touched scarlet; Messrs. Wells being second with Mrs. T. A. Weston, apricot with scarlet markings.

Dinner table decoration of Carnations, 8 feet by 4 feet (no cutlery allowed): Five competitors entered, the first prize going to Messrs. R. F. Felton and Sons, Hanover Square, W., who employed vases of Lady Northcliffe, associated with trails of bronze Ivy, Asparagus and sprays of Azara microphylla. Second, Mrs. A. E. Brown, Reigate, who had Salmon Winsor, with Croton leaves, Asparagus and Cyperus; third, Mrs. Alex. Robinson, Carshalton, the same variety being associated with Ivy, Pittosporum, Asparagus and Grasses. All the arrangements were well placed.

SECTION B (GARDENERS AND AMATEURS).

For the Lord Howard de Walden Challenge Cup and a cash prize of £3 as first prize for a semi-circular group of Carnation plants in flower, 25 square feet being allowed, only one competitor, Sir Daniel F. Gooch, Bart., Hylands Park, Chelmsford (gardener, Mr. W. Heath), entered, occupying the corner near the annexe. Well-grown, well-flowered, dwarf, lightly and neatly staged, the perfection of cleanliness and healthy vigour, this admirable lot would have required some beating in any competition, hence merited high praise while standing alone. The varieties were not named, and while a display of names on cardboard might constitute a disfigurement in the case, we certainly think that from the educational point of view a side plant of each variety could be named without detracting from the merit of the group. White, crimson, rose pink and salmon shades were fairly evenly balanced.

For one vase of a British-raised seedling, the Countess of Derby, Sunningdale (gardener, Mr. G. Reed), was first, Sir Randolph Baker, Bart., taking the first prize in the

following class for twelve blooms from a given list of nine American sorts. The variety staged was Pink Perfection, the flowers very fine.

For twelve plants in bloom of three or more varieties of Mr. Engelmann's introduction, the Engelmann Novelty Cup and money prizes were offered, the first prize going to Sir Randolph Baker, Bart., Blandford (gardener, Mr. A. E. Usher), who set up well-dowered Triumph, Sunstar, Lady Northcliffe and Fanny (fancy). Second, Mr. A. H. Hartley, Ridgmead, Englefield Green, who had Sunstar, Harlequin, Triumph, Carola and Pioneer. The third prize was awarded to very poor examples staged by Mr. W. Heath, gardener to Sir Daniel F. Gooch, Bart., Chelmsford.

For five blooms of Enchantress, Lady Meyer, R. F. Felton or like shade, eight competitors staged, Mr. G. J. C. Harter, The Grotto, Reading, being first with R. F. Felton; Mr. G. Lloyd Wigg, showing Enchantress Supreme finely and taking second prize.

Eleven exhibitors staged in a like class, where Baroness de Brien, Lady Northcliffe and other colours akin were the selected varieties. First, the Countess of Derby, Sunningdale (gardener, Mr. W. J. Reed), who had Baroness de Brien; second, Mr. W. E. Thornber, Burnley; third, Mr. G. J. C. Harter, Reading, the specimens in both being unnamed. In view of Regulation 6 (page 10), that "all flowers in the competitive classes must be plainly and correctly labelled," and, further, that "single vases not so named will be liable to disqualification," we wonder why, in so well contested a class—or, indeed, any class—the regulation was not enforced.

In the Rose Pink Enchantress, Winsor and allied colour shades, five blooms, seven exhibits were staged. Sir Randolph Baker, Bart. (gardener, Mr. Usher), was first with Good Cheer; second, Captain D. Macpherson, R.N., West Coker, Yeovil, who had Rose Pink Enchantress; third, Sir Daniel Gooch, Bart., with the same variety.

Mrs. Mackay Edgar, a pink-flowered British novelty raised by Messrs. Stuart Low and Co., Enfield, was the only variety to which an award of merit was granted. It received 78 points.

NON-COMPETITIVE EXHIBITS.

Mr. A. F. Dutton, Iver, staged a very fine exhibit of the varieties Chelsea (fancy), and Louvain (self red). Mr. George West, Gables Nurseries, Datchet, arranged a floor group of admirably grown examples of Nora West, of lovely salmon pink shade. Mr. J. C. Jenner, Rayleigh, had superb vases of Snowstorm, Lady Northcliffe, Enchantress Supreme, Champion, White Enchantress and others. Messrs. Laxton Brothers, Bedford, contributed well of their British-raised seedling Bedford Belle, a variety of great promise, fragrant, rosy salmon in colour, and of great freedom. The colour is singularly bright and effective. Messrs. Allwood Brothers, Hayward's Heath, arranged a most artistic grouping of the flowers, Mary Allwood and Wivelsfield White being strongly in evidence among many. Messrs. Stuart Low and Co., Enfield, had an excellent lot, in which the certificated Mrs. Mackay Edgar loomed largely, also Matchless and White Wonder, two of the leading whites.

An attractive and extensive exhibit, composed of *Liliums longiflorum* and *speciosum*, *Lily of the Valley*, *Chrysanthemums*, fruit and *Begonia Gloire de Lorraine*, arranged and given chiefly by Mr. W. H. Page, Tangley Park Nursery, Hampton, was presided over by the Misses Page, the Misses Sherwood and Miss Dolly Mason, the proceeds of the sale to be devoted to the Royal Horticultural Society's War Relief Fund. We hope this admirably conceived project received the support it merited.

BOOKS.

The Greenhouse: Its Flowers and Management*—This is one of the many gardening handbooks issued by Messrs. Cassell, and that, too, at a very cheap rate. Its 151 pages are replete with information such as the amateur requires, commencing as it does with the construction of the greenhouse and its heating, following on with plants suitable for that structure and their culture. To the amateur taking up the culture of greenhouse plants this book can be confidently recommended, as the instructions are clear and concise, and greatly helped by the numerous illustrations. A common error of assuming that the amateur knows more than he really does is altogether avoided. The book shows evidence of care in its compilation, but a slight slip or two may be pointed out. On page 34 the description of the *Grevillea* applies to *Grevillea robusta*, but, as there are so many other kinds, the specific name should have been given. The *Begonia* on page 44 should read "*weltoniensis*," not "*meltoniensis*," while exception may be taken to *Geonoma gracilis* as one of the most accommodating of Palms.

* "The Greenhouse: Its Flowers and Management," by H. H. Thomas. Cassell and Co., Limited, La Belle Sauvage, E.C.; price 1s.

THE GARDEN.

No. 2301.—VOL. LXXIX.

DECEMBER 25, 1915.

NOTES OF THE WEEK.

To Our Readers.—With this issue we bring to a close Vol. LXXIX. of THE GARDEN, and we take this opportunity of expressing our warm thanks and appreciation to the many contributors who help to make our pages interesting and replete with practical suggestions. THE GARDEN is singularly fortunate in numbering among its contributors the leading horticultural authorities in the land. Our contributors include Edwin Beckett, V.M.H., George Bunyard, V.M.H., E. Molyneux and Owen Thomas, V.M.H., experts on fruits and vegetables; Miss Jekyll, S. Arnott, W. Irving and E. H. Jenkins on border flowers and rock plants; W. Easlea and Herbert E. Molyneux on Roses; the Rev. Joseph Jacob, who writes exclusively for THE GARDEN on Tulips, Daffodils and kindred subjects; Sir Herbert Maxwell on Lilies; and W. J. Bean, W. Dallimore and Dr. W. Botting Hemsley, F.R.S., on trees and shrubs. Among those who have expressed their willingness to contribute occasional articles in coming numbers are Miss E. Willmott, V.M.H., J. T. Bennett-Poë, V.M.H., E. A. Bowles, F.L.S., E. A. Bunyard, F.L.S., F. Herbert Chapman, F. J. Chittenden, F.L.S., the Rev. G. H. Engleheart, V.M.H., James Hudson, V.M.H., E. Mawley, V.M.H., and Charles E. Shea, V.M.H. In the New Year, Mr. George Dillistone will commence a new and helpful series of articles on how to lay out a garden; and Mr. W. F. Rowles will start a series of useful articles on the greenhouse for food supply. A general index, together with a title-page and frontispiece suitable for binding all the numbers published during 1915, is presented with this issue. Next week we shall publish our Special New Year Number; and as there is always a large demand for the New Year issue, we advise readers to order their copies well in advance.

The Gardens of Lowther Castle.—We are indebted to the Earl of Lonsdale for kindly sending the illustrations to accompany the Rev. David R. Williamson's description of the gardens of Lowther Castle which appears in the pages of this issue.

The Late W. Atlee Burpee.—The Rev. David R. Williamson writes from Kirk House, Kirkmaiden, N.B., on December 18: "I have been greatly grieved on hearing the sad news of the death of that supremely gifted horticulturist, Mr. W. Atlee Burpee of Philadelphia, who was my kindest American friend. How I will miss

the singularly fascinating letters regarding the latest and loveliest varieties of the Ipomœas and Sweet Peas he used regularly to write me at this season of the year! His outward form has vanished for ever, but his influence remains, a never-dying grace, an ineffaceable possession, to inspire us still."

Home-Grown Timber Committee.—The President of the Board of Agriculture and Fisheries

Government purposes. All communications for the committee should be addressed to the Secretary, Home-grown Timber Committee, Craven House, Northumberland Avenue, W.C.

The Aubergine or Egg Plant.—By many the Aubergine is regarded as an article of food. Even where its merits in this respect are not appreciated, it forms a decidedly ornamental feature in the greenhouse, the fruits retaining their brightness for a considerable time, which is a great point in favour of the Egg Plant, as it is popularly termed. The two commonest forms are the white and purple, while different intermediate shades occur among them. The most effective is the white-fruited form, as in its clear milk-like tone of colour it stands out quite distinct from any other berried or fruiting plant in the greenhouse. It is a member of the great Solanum family, the botanical name being Solanum Melongena. All that is necessary in its cultivation is to sow the seed in gentle heat in spring, and pot on the young plants, when required, in good soil, giving them much the same treatment as Tomato plants. Fruiting examples may be grown in 5-inch, 6-inch or 7-inch pots.

A Beautiful Golden Cypress.—Cupressus or Retinospora obtusa var. Crippsii is one of the most distinct and pleasing yellow-leaved conifers cultivated in our gardens. Attractive at all seasons of the year, it is especially prominent and valuable at the present time. A tree of moderate dimensions, Cripps' Golden Cypress is worth planting as a lawn specimen even in comparatively small gardens, and in groups for extensive pleasure grounds or wide shrubbery borders. Cuttings provide a ready method of propagation.

Cotoneaster rotundifolia.—First introduced from the Himalayas nearly a hundred years ago, this Cotoneaster is one of the four best species cultivated in our gardens. The bright red fruits remain on the bushes until February or March untouched by the birds. It is a shrub 4 feet to 6 feet high, occasionally more, and though not strictly evergreen, many leaves persist through the winter, and only seem to disappear with the development of young leaves in spring. At Kew just now a bed of about a dozen plants near the Orchid Houses is very effective, particularly when the branches are glistening in the sun.

THE AUBERGINE OR EGG PLANT. THE ATTRACTIVE FRUITS ARE PALATABLE WHEN FRIED.

has appointed a committee for the purpose of making such arrangements as are likely to ensure the fullest use being made of native resources in supplying existing demands for timber. The committee are prepared to purchase standing timber and to make arrangements where necessary for felling, hauling and conversion; they will be glad to receive particulars of timber which landowners and others would be willing to sell for

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Magenta Flowers.—May I add two names to the list of magenta flowers given by Mr. Clarence Elliott in reply to "Magenta's" query? *Lathyrus Sibthorpii* blooms early, and is a really bright and delicate shade of this generally unpleasing colour; and a variety of *Primula ciliata* has the most brilliant magenta flowers, noticeable from a good distance, and quite the best, in my mind, of the colour. I would not call *P. pulverulenta* magenta at all. It should surely be classed as crimson.—H. M. B.

A Pretty Combination.—There is a raised mound for Yuccas with three courses of dry walling next the path. At the top of this, and running in 2 feet or 3 feet till the smaller Yuccas are reached, there is first a planting of *Heliotrope* and then one of *Ivy Geranium Mme. Crousse*. The latter is planted rather thinly, and is carpeted and front-edged with *Sweet Alyssum*, which is also sown in the joints of the dry walling. The pink and white, following the purple, has such a charming effect that it may be confidently recommended; indeed, in any place where the useful *Ivy Geranium Mme. Crousse* is employed, the addition of the *Sweet Alyssum* will be found desirable.—G. JEKILL.

Daffodils in December.—It sounds early to be having Daffodils in flower in mid-December, but thereby hangs a little story. Some years ago I made some crosses between *Tenby* (*obvallaris*) and *pallidus præcox*. Some of these have grown into little stocks, and being of small or no commercial value, we potted some of them up this year and plunged them outside in fibre early in September. In November they were brought into a house kept at about 60°, and the first flowers opened on December 15, so that from now till next May we shall not be without Daffodils. An essential which should never be forgotten when getting these early forced flowers is to keep the plants constantly sprayed, otherwise most of the buds will go blind.—F. HERBERT CHAPMAN.

Origin of the Name Traveller's Joy.—*A propos* the notes and illustration on *Traveller's Joy* (*Clematis Vitalba*) as a wayside plant, issue December 4, page 592, the origin of the name *Traveller's Joy* can be traced to Gerrard, as may be seen from the following quotation, taken some years ago from an old herbal which I have since lost sight of. Because of its "decking and adorning the ways and hedges where people travel," says Gerard, "I have named it the *Traveller's Joy*." Verily, no plant could have been more appropriately named than the subject now adding beauty and interest to our lanes and hedgerows by virtue of its downy fruits.—HURSTGATE.

Borecole Injured by Frost.—Many plants of Borecole, or Kale—Dwarf Green Curled variety—have suffered much from the hard frosts which we have had almost continuously since November 11. The young leaves are yellowish brown

round the edges, and even many of the older leaves are similarly affected. A number of the plant stems and leaf-stalks are also bleached in appearance. In fact, some of the plants are lying over, while others will be of no use. The most forward plants appear to have suffered most.

DAVID ARMSTRONG, *Kirknewton, Midlothian*.

***Buddleia globosa*.**—This is one of the prettiest of shrubs, with its tongued, soft green leaves and orange ball flowers. It is very easy to grow, as it strikes readily from cuttings inserted in the open ground almost at any season of the year. I look on it as a gem among shrubs, and would class it with *Choisya ternata* and *Cytisus andreas*. It is more familiarly known as the Orange Ball Tree, and came originally from the plains and mountains of Chile. It is much grown here in the North of Ireland, and its flowers are locally named King William's Buttons. It is best planted in shelter, as its roothold is not very secure, giving easily in high winds. There are other varieties, but I like this one best.—WALTER SMYTH, *Holywood, County Down*.

FLOWERS OF THE ORANGE BALL TREE (*BUDDLEIA GLOBOSA*).

Rose Rayon d'Or.—This beautiful Rose has a reputation as a poor doer and liable to die back badly in the winter. Lately I sent a photograph of a bed of twelve plants of this variety to the raiser, M. Pernet-Ducher, who expressed himself as much surprised at the vigour of the plants, which are 3 feet high. Since they were planted in 1912 they have been a mass of bloom nearly the whole summer each year. I hope my experience will encourage others to plant this Rose and not be put off by a reputation which is quite undeserved. I am afraid I have no secret to divulge as to the success with *Rayon d'Or*, as my soil is pure sand. The bed was taken out about 3 feet and filled in with a mixture of strong clay, loam and leaf-soil, well turned over together. Of course, strong plants must be procured. I prune hard and, when the plants are established, manure liberally with Voss' Special Rose Manure, generally giving three applications in the season, February, April and July, but not too much at a time. Before planting a bed I tried two plants for

a season, putting them among the other Roses in the Rose garden in a less strong soil; they did equally well as in the bed. My plants are in a sheltered position and full sun all day. In September of this year I returned home to find the Rose garden practically leafless, and the Roses wrecked by mildew and black spot, except *Rayon d'Or*, which unharmed by either, was a mass of lovely blooms, almost as yellow as Buttercups.—C. G. O. BOND, *Churt, Surrey*.

***Lilium giganteum*.**—My offer to send seed of this Lily has brought me exceedingly numerous requests for the same, all of which I hope to fulfil in the course of a few days. But it is quite out of my power to reply severally to those who ask for cultural instruction. Perhaps they will allow me to reply briefly through *THE GARDEN* to their enquiries. The seeds should be sown at once in boxes filled with a compost of loam, sand and peat or leaf-mould in equal proportions, and lightly covered with sand and pulverised leaf-mould. No lime should be used at any period of growth. The boxes should be kept in a cold

frame or cool greenhouse through the winter, keeping the soil moist, but not wet. Some seeds will probably germinate next spring; the majority not till the second year. So soon as the seedlings are fit to handle, having small bulbs, they may be pricked out in the open, but not exposed to scorching sun. In cold districts a screen of branches or matting should be laid over them in winter. In proportion as the bulbs increase in size, the soil should be enriched with well-rotted manure. When they approach the flowering stage, which will be in their sixth to eighth year, it is hardly possible to treat them too generously. If the staple diet is deep peaty loam, the Lily will respond gratefully to strong food. In planting out for permanence, choose a place sheltered from rough winds, in partial shade (not overhead), and set the bulbs with the pointed top only just underground. The bulb perishes after flowering, but not before producing numerous offsets. Allow me to thank some of my correspondents for their

kind gifts of various seeds in exchange.—HERBERT MAXWELL, *Monreith*.

The Strawberry Tree (*Arbutus Unedo*).—This most attractive evergreen shrub, *Arbutus Unedo*, is said to be indigenous to the southern climes of Europe, the region of a cruel war. The locally named Strawberry Tree is known to grow luxuriantly in England and Wales; and where protected from cold, deteriorating draughts the plant forms an admirable addition to the shrubberies of even some Lancashire gardens. While in its gayness of fruit and flower, specimens of this curious plant came as a botanical favour to certain Ashtonians in Lancashire from the mountainous grounds of an Ashton lady, at times resident in Abergele, North Wales; but the plant is fairly well cultivated around Manchester. *Arbutus Unedo* is classified in the Natural Order Ericaceæ, thus is a kindred plant to our mountain, low-lying plants, such as the Bearberry, Cranberry, and *Arctostaphylos Uva-ursi*, a familiar diuretic with herbalists;

but, while these latter plants grow shrubby and low on the hillsides, the *Arbutus* sometimes develops into a fine tree, from 8 feet to 10 feet high, in varied plantations. The close character of the surrounding branches seems to increase by a dichotomous or furcate growth. [The same characteristic is noticeable in *Arbutus Menziesii*; see accompanying illustration.—ED.] As may be noticed in a complete specimen, the former year's branches, perhaps now retaining the berries, may also during the second season have grown two opposite branchlets, each bearing a raceme or pendant of pinky white flowers, which, again, by the following autumn will have developed a number of red, Strawberry-like berries. Thus, by the time the berries have attained their scarlet colour, the secondary side branches are also in beautiful flower, and in drooping whiteness are awaiting fertilisation.

Darwin Tulip Elephant.—I never omit to read the Rev. Joseph Jacob's interesting articles in your valuable paper, and so I saw him use my name in much too flattering terms. Happily, I am now able to assist him. Oliphant is the Dutch equivalent for Elephant, and so I think Dutch people, when issuing English catalogues, should write Elephant instead of Oliphant, as well as Queen of the Netherlands instead of *Köningin der Nederlanden*.—JAN ROES, *Heemstede, Holland*.

The Four Best Dessert Apples.—I read with interest the article appearing in the issue of November 31 on "The Four Best Dessert Apples." If I were planting only four trees, I certainly should not omit James Grieve. It is a most beautiful Apple, and I consider everyone should include it if possible. It is a splendid cropper, and the Apples are of good size. I came across a nursery catalogue the other day in which this variety was not even listed; why, I cannot understand. In my opinion it is unsurpassed in its season.—E. A., *Thornhill, Copmanthorpe, York*.

Eucalyptus globulus Planted Out in a Cool Conservatory.—Except in a young state, this vigorous tree does not usually look very happy when grown in a pot, but a few years ago I stumbled upon a success with it planted out in a cool conservatory here. Two plants in 6-inch pots were, along with some Palms, *Dracænas*, &c., stood on the surface of a bed in the centre of the house. The bed entirely consists of rough shingle, overlaid with a thin layer of clean sea gravel. After some time it was evident from the vigorous top growth that the Blue Gums were rooting into the bed. Left undisturbed, they grew rapidly, and in less than a year they burst their pots, and were then at the roof of the house fully 12 feet high. After using the young shoots for filling large vases during the winter, the trees were sawn over in the spring about 4 feet from the floor, and this is carried out annually and gives great satisfaction. In the cut state the lovely glaucous grey, health-giving shoots last quite a fortnight.—CHARLES COMFORT, *Broomfield Gardens, Midlothian*.

English v. Latin Plant Names.—Mr. Murray Hornibrook, in the issue of November 27, discusses on the right topic at the right time, and I

heartily agree with every word he says on the subject. I have seen catalogues compiled in the way he describes, also advertisements in some of the gardening papers offering plants, giving only the "English" and not the botanical names. This matter is serious on account of the confusion that will arise if the system is carried out too far; it wants nipping in the bud and stopping at once. Surely amateurs can be persuaded that the Latin names are essential and not difficult; surely they can be persuaded not to buy plants offered in the "English" names only. If they cannot, they will lay themselves open to have all sorts of undesirable plants under "enticing" English names.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

Apple Lane's Prince Albert.—Among thirty varieties grown in my garden for twelve years, this has been the most regular cropper, only failing once, in a very unfavourable season, and

CHRISTMAS ROSES.

(HELLEBORES.)

AT several of the recent exhibitions the pearly white Christmas Rose, the fairest flower of winter, has been shown in many varieties; and these little displays of one of the hardiest of perennial plants remind us of the scarcity of Hellebores in English gardens. We wish the pretty way of planting the Christmas Roses in the Royal Gardens, Kew, were more adopted. There they are among Ferns on the fringe of woodland, and peer up from the foliage a mantle of white for several weeks. Snow seems to have fallen on this woodland, and the brown Fern fronds afford some protection. Winter in the country is not the depressing season so frequently depicted, and on many days, with the sun

ARBUTUS MENZIESII SHOWING DICHOTOMOUS BRANCHING.

even then having a few fruits, when other kinds were bare. If I could have but one Apple tree, I would choose Lane's as the best cropping, cooking and keeping, all round variety, and also as one having particularly beautiful blossom. Though I commend Lane's thus highly, I do not use it for my mincemeat. The Apple we used was one growing in the dear old Surbiton garden, a small lemon-coloured one, with tiny black dots on its thin, tough skin. It was very hard and sour, and I do not know its name.—ANNE AMATEUR.

An Excellent Melon.—Several years since I recommended readers of THE GARDEN to try the variety Triumph. For growing in pits we still find this Melon a most reliable sort. The plants are vigorous, the fruit sets freely, and the flavour is pronounced excellent. We find this variety gives more satisfaction than the popular Hero of Lockinge or Ringleader. This Melon is bound to become increasingly popular.—COLIN RUSE.

shining brightly, the Christmas Roses have lifted up their white petals to catch every ray. The plants at Kew are growing in ordinary sandy loam, without any manure, and the only assistance they derive is from the top-dressing of decayed leaves used for the Ferns among which the Christmas Roses are growing. Shaded on the east and south by trees, the sun only shines upon them during the afternoon and evening. One point of importance that should be noticed by those who have not had much success with this flower of winter is the moisture the plants receive during the summer months. The Ferns are frequently watered, and the moist soil is favourable to the Hellebores. One is apt to forget during the rest of the year the plants which flower in winter and spring, although it is during the summer that water and mulching are desirable. A well-known grower of Hellebores writes: "Their chief requirements are shade during the hottest part of the day, deep culture in rich, loamy soil,

and liberal supplies of water during the growing period."

There are many varieties, differing considerably in the size of both flower and leaf, some retaining their foliage much better than others. The most popular form is known as *Helleborus niger* (the botanical name of the Christmas Rose) *altifolius*; it is also called *major* and *maximus*, and has large buds and white flowers shaded with red; these are 4 inches to 5 inches across. Another distinct and pretty form is *angustifolius*, which has smaller flowers than *altifolius*, and of the purest white; while *Mme. Foucarde*, the *Riverston* and *St. Brigid* are all beautiful. *Mme. Foucarde* is valuable for its late flowering. Nothing is more delightful on the Christmas dinner-table than this lovely flower, so appropriate to the season; but we never trust to the outdoor plants for supplying this decoration. The flowers, even under the happy conditions in which the plants are placed at Kew, are frequently sullied by wind

latifolia and *Ranunculus aconitifolius* fl.-pl., better known as *Fair Maids of France*. Then, again, *Rudbeckia Newmani* makes a handsome display when grown in a bed by itself. It never fails to flower with great freedom, its rich orange yellow florets contrasting well with the velvety black purple disc that gives to the genus the popular name of *Cone-flowers*. In a moderately rich light and well-drained soil this hardy perennial which may be planted now, is one of the easiest plants to grow. *Rudbeckia Newmani*, like many another beautiful garden flower, has had the misfortune to bear other botanical names. It is synonymous with *R. speciosa*, and has also been called *Obeliscaria speciosa*.

PARSLEY IN WINTER.

A good healthy batch of Parsley in winter is always greatly appreciated, but sometimes all

the soil must be loosened on the surface and a dressing of gritty soil and leaf-soil put on nearly 2 inches deep. The old plants, so treated, will withstand an ordinary winter without any protection. If plants are to be lifted and replanted in frames, those raised last spring are the best for the purpose. Use a garden fork when lifting the roots, so as to preserve them; trim off the outer leaves and replant in a bed of soil 1 foot deep, making the soil firm. Remove the glass lights in fine weather.

G. G.

SOME SOURCES OF FLOWER FRAGRANCE.

I SUPPOSE no garden-lover would deny that the most precious attribute of a flower is fragrance, and, that being so, the question which naturally arises in the mind is, do we make enough of it, or are we content to accept it as and when it comes? In certain walks of life we are bidden to embrace opportunities; in gardening we may do worse than seek out all plants endowed with fragrance, be it of leaf or stem or flower. In this connection and in these days of specialisation when certain parts are given up to the "wild garden," the "blue" and "white" garden, and others full of costly, if meaningless statuary, or the too frequent evidence of the barber-gardener, one is tempted to urge the claims of the fragrant garden, a spot to which only sweet-smelling things should be admitted. Less attractive than some, and devoid of garishness, such a garden would be full of interest at all times, while the variety alone that would be admissible would probably surprise even those who set out to establish it.

Such a garden, indeed, may have its beginning with the *Winter Sweet* (*Chimonanthus fragrans*) and may finish with the *Winter Heliotrope* (*Petasites fragrans*), which often, by the way, join forces. Between these the way might well be strewn with *Wallflower*, *Rocket*, *Sweet Sultan*, *Violets*, *Mezereon*, *Sweet Bay*, *Stocks*, *Mignonette*, *Tobacco*, *Night-scented Stocks*, *Lemon Verbena*, *Sweet Briar*, *Lavender*, *Rosemary*, *Balm*, *Lilac*, *Pennyroyal*, *Thyme*, *Honeysuckle* and *Lily of the Valley*, to say nothing of the nobler flowers of the garden, *Lilies* and *Magnolias*, and the modern race of *Hybrid Tea Roses*, which, by reason of its variety and continuity, takes precedence of them all. Just how much of this fragrance it is possible to have in any one garden is not unnaturally very much a question of ways and

A BEAUTIFUL BED OF RUDBECKIA NEWMANI IN LATE SUMMER.

and rain. We therefore lift a certain number of clumps when the buds are showing, and put two together, or, if very large, only one, in a bushel basket filled with light, loamy soil. They are then taken to a warm greenhouse, and it is astonishing how quickly the buds develop, opening out as pure as snow. It is a simple matter to force—if we may so call it—the Christmas Rose, and *altifolius* is the best variety for the purpose.

RUDBECKIA NEWMANI.

THE orange-flowered *Rudbeckia Newmani* and the deep rose *R. purpurea* are good summer and autumnal flowers. They look exceedingly pretty in the hardy flower border mingled with *Scabiosa caucasica*, valuable for its porcelain blue flowers; the Californian *Romneya Coulteri*, with deliciously fragrant, flimsy white flowers and central boss of golden anthers; *Globe-flowers* (*Trollius*), *Statice*

efforts on the part of the cultivator fail to ensure a nice crop of leaves. In certain plots it will grow, while in others in the same garden it will fail. The reasons for the failure in such circumstances are entirely local. The following hints, however, will be useful to those who wish to have Parsley throughout the winter. Very young plants often fail, while those raised not later than last May will succeed. If young plants only are now available, they must be thinned out severely that is, to 9 inches apart. When allowed to grow in a very crowded condition and get wet and frozen alternately, they damp off wholesale. The leaf-stalks of the plants that have been thinned out are shorter and much stronger, and withstand severe weather very well indeed. Where old plants only are available for winter use, the outer leaves should now be stripped off—not cut, leaving the stumps of the stems—and only the central leaves. Between the rows of plants

means, and, of course, but a fragment of the sweet-smelling things of the earth is contained in the foregoing list. So great is the variety, indeed, that in treating of this subject one could but touch on the more important things in the hope that, by directing attention thereto, the wealth of material existing might receive more adequate attention.

Sweet Violets.—Of the flowers of the moment, and such as afford a plenitude and succession through many weary months, no easily grown hardy flower is more precious than the Violet, albeit few are more indifferently cultivated. The reason is not far to seek. Violets in rich soils and shady places make luxurious leaf growth and, spreading freely, afford the unthinking gardener an excess of material which does not make for good. To divide big clumps of these after flowering is easy enough, though infinitely superior results are the outcome of securing the unflowered runners as cuttings during the autumn months. Such as these, rooted and planted out in April in moderately rich soil and in places not too shaded; make the finer crowns for winter flowering because favoured with greater vitality and youthfulness as compared with the somewhat exhausted examples that have done a season's work.

Lavender, Southernwood and Rosemary.—Walks or borderings may all be planted now, employing preferably youthful examples of a year or two old, raised from cuttings. Culturally it is well to remember that the Lavender is a lime-loving subject, and while lime is by no means essential to its existence, it is certainly benefited by its presence. There are several varieties, and in addition to that usually grown and its white-flowered form, mention should be made of the Munstead variety and others known as nana or compacta, any of which are suitable for gardens of limited size. Among Lilies which might well be planted, none merits more attention than the

Madonna Lily, which for generations has graced many a cottage garden. Purest of its tribe, it is also one of the most fragrant, a fragrance that can be endured. Lover of rather poor soil and suited to the warmer, sunnier places of the garden, it is unlike not a few of its race, which possess a preference for cool and shade. When planting it in the garden, good effects may be secured by grouping it in the forefront of sombre-leaved evergreens, as Yew or Holly, the association mirroring the twain into fuller life and beauty than would be possible otherwise. *Lilium odorum*, *Brownii* and *regale*, all members of the trumpet section of Lilies, are other fragrant sorts that might be planted, with, as soon as they come to hand, the golden-rayed Hill Lily of Japan (*L. auratum*) and its variety *platyphyllum*. Powerfully fragrant, these should be reserved for the outdoor garden, where, associated with low-growing shrubs—valuable as a protection against spring frosts and of not a little service by reason of root companionship—they not infrequently do well. These latter are of the stem-rooting class of Lilies, and should be planted at least 6 inches deep and given fairly rich soil. Quite one of the most charming of fragrant plants of a bulbous character is the

Gardenia-scented Narcissus (*N. Poeticus fl.-pl.*), much less grown than it should be, because it is prone to so-called "blindness." This, however, is chiefly due to a cultural error—a

lack of knowledge as to its requirements. Impatient of root disturbance at all times, it is a mistake to plant it in shallow soils or those of a sandy or dry, hot nature. In cool, moist or even wet loam—I have been most successful with it even as a subaquatic, where the root fibres were in touch with moisture at all times—"blindness," so called, is practically unknown. By growing it under these or like conditions, inserting the

particularly good this autumn, and Hugh Dickson likewise. Then, in any select list, such as Queen of Fragrance, Mrs. George Norwood, Lady Alice Stanley, Laurent Carle, George Dickson, Earl of Gosford, Alexander Hill Gray and Mrs. E. Powell (rich velvety crimson) should be included by reason of fragrance alone, though naturally they constitute but a fragment of a far greater whole. There are garden Pinks that grow like

MADONNA LILY AND ROSE HELENE IN A BORDER OF FRAGRANCE.

bulbs 6 inches or 8 inches deep and letting it alone, it will give, when established, a plenitude of pure white, fragrant flowers in late spring that will repay the little trouble involved.

And then there are the Hybrid Tea and other Roses—most precious of fragrant-flowered plants—galore, and of greater value because of their constancy and the richer garb they assume in favourable seasons. Lady Hillingdon has been

weeds, but which deserve well at the hand of the gardener for the precious attribute we have in mind; Bergamot, and other things; while such subjects as Thyme and that inimitable carpeter, *Mentha Requienii*, may, with others, be reserved for those favouring paved walks or the like, where the least movement or friction will set at liberty that in which all garden-lovers delight—fragrance of a unique kind. E. H. JENKINS.

THE GARDENS OF LOWTHER CASTLE.

By THE REV. DAVID R. WILLIAMSON.

DURING a recent visit to the English Lakes I walked from Penrith to Lowther Castle, the famous residence of the Earl of Lonsdale in Westmorland, to see for the first time the spacious gardens there.

I had a memorably cordial reception from the highly capable and accomplished head-gardener, Mr. James Jeffrey, whose kindness and courteous attention on this special occasion I will not soon forget. His father, I may here state, incidentally, superintends the gardens at St. Mary's Isle, Kirkcudbright; and his brother, those of Sir R. Buchanan Jardine at Castlemilk in Dumfriesshire; so it may be inferred that his is an intensely horticultural family. I would require—as I frankly told Mr. Jeffrey—to visit the Lowther Castle gardens many times and study them very attentively, with adequate appreciation of their widely varied floral, arboricultural, and pomological attractiveness, before I could dream of exhausting such a rarely comprehensive subject. There can be no question that in their gradual evolution (or artistic development) the Earl of Lonsdale, recognising their possibilities, has spared no expense. His Lordship, while quite naturally—and hereditarily—devoted to healthful, energising sport, has a warm region in his wide and generous heart for beautiful trees, especially when they are of historic interest; and a fine avenue of Yews, on the confines of the gardens, is one of his favourite haunts. He is pardonably proud of being their possessor; for like those which I have seen at Craigmillar and Rosslyn Castles in Scotland, they have every appearance of being centuries old. On every side environing his magnificent castle—in happier times much visited by the Kaiser of Germany—are stately woods (once immense forests frequented by wild horses) embracing many majestic trees, especially Oaks, and Elms and wide-spreading Sycamores, radiant, at the period of my visit, with rainbow hues. Mrs. Hemans' ideal of the "Stately Homes of England," so musically embodied in one of her finest poems, is idealised here.

"The deer across the greensward bound,
Through shade, and sunny gleam;
And the swan glides past them, with the sound
Of some rejoicing stream."

The silvery sounding of chimes from the great castle every quarter of an hour comes, ever and anon, like distant music amid the silent woodlands to the raptured consciousness of the lover of Nature, who cannot be less than inspired, like Wordsworth or Mrs. Hemans, with such a scene. The cannon that seem to frown around the battlements and terraces only emphasise the

conception—even in the present period of agonising war—that this is a region of perpetual peace.

I visited Lowther Castle gardens in the middle of October—that sunset of the year—saddening with all its glorious, transitory, autumnal hues; much too late for the vast majority of its myriad displays of infinitely varied flowers. On the herbaceous borders they had for the most part disappeared for a period of silent, yet earnest preparation, the subtle, mysterious process of

AN AVENUE OF BEECHES IN THE BEAUTIFULLY WOODED GARDENS OF LOWTHER CASTLE.

root production, till they are touched into wondrous energy next summer by the great annual resurrection. But in the conservatories there were many exquisitely lovely Gardenias, supreme favourites of Lord and Lady Lonsdale; golden-hued Allamandas; radiant Orchids, the aristocracy of flowers; and fragrant Carnations, reminiscent of the original Malmaisons, which can no more become superfluous than such Roses as *Devoniensis*, *La France*, *Maréchal Niel* and its richly endowed derivatives; or the venerable and much-loved *Gloire de Dijon*. Very fascinating were the Iris and Japanese garden; show much more impressive, then, had I only seen them in their virginal, luxuriant bloom! There was a grand exhibition of early flowering Chrysanthemums; and the marvellous multitude of glowing,

embryonic flower-buds visible in the conservatories—the peculiar glories of winter—indicated a more radiant revelation yet to come.

Lowther Castle, with its gracious gardens and its majestic environment of noble woodlands and floral terraces, will long abide, like inspiration, in the regions of memory.

OUR NATIVE TREES AND THEIR CONGENERS.—IV.

By W. BOTTING HEMSLEY, LL.D., F.R.S., V.M.H.

The Bird Cherry, Blackthorn, Bullace Cherry and Plum (*Prunus*).—The subfamilies Prunoideæ

and Pomoideæ of the Rosaceæ include nearly all of our most important hardy fruit trees, and some of these now exist in a wild condition nearly all over the kingdom; but most of these are probably descendants of escapes from cultivation. To the first of these subfamilies belong, in addition to those named above, the Peach and Apricot, the common and Portugal Laurels, &c. The fruit of these is distinguished from that of the Pomoideæ by having no "eye" at the apex, such as the Apple has, for example. *Prunus* is a very large genus, comprising probably 200 species, of which upwards of sixty inhabit China, the majority of these being peculiar to that country. The genus is scattered all round the Northern Hemisphere, chiefly in temperate and subtropical regions, and in America it ranges from Canada through the mountains of Mexico and Central America to the Andes. It is apparently absent from Tropical and South Africa, Australasia, and Polynesia, where also no closely allied members of the subfamily exist. The Gean (*Prunus Avium*), the Bird Cherry (*P. Padus*) and the Blackthorn or Sloe (*P. spinosa*) are generally considered to be true natives of this country.

The Crab (*Pyrus*).—The Apple, Pear, Mountain Ash or Rowan Tree, Wild Service, &c., are members of the genus *Pyrus*, and some botanists consider the Quince (*Cydonia*) and the Medlar (*Mespilus*) as congeners. Altogether about seventy species

of *Pyrus* are on record. They are almost confined to the north temperate and sub-arctic zones. Few species inhabit America, none reaching so far south as Mexico. The greatest concentration of species is in Eastern Asia, which is the home of most of the ornamental and some of the useful kinds.

The Hawthorn or Whitethorn (*Crataegus*).—*Crataegus* is confined to the north temperate regions, the southern limit being the mountains of Colombia, where one species, at least, has been collected. *C. stipulosa* has, however, been recorded from Mexico, Guatemala and Peru. The genus is spread all round the Northern Hemisphere, and is most numerous in North America, the number of species having been variously estimated at thirty to fifty. But of

late years several American botanists have made a special study of the North American species and multiplied the number to about a thousand. *Cratægus*, like *Rubus*, is very plastic, and the majority of these species are highly critical. The *Pomoideæ* are exceedingly rare in the Southern Hemisphere; but there is an Andine genus, *Osteomeles*, closely allied to *Cratægus*, of one (or perhaps more) species, *O. anthyllidifolia*, which ranges from China and Japan eastwards, across the Pacific, to Hawaii, Pitcairn, Mangaia and other remote islands. This species is not Andine, and its remarkable distribution may be due to birds, oceanic currents or indirect human agency.

The Spindle Tree (*Euonymus*).—The sole British representative of the genus *Euonymus*, *E. europæus*, is only exceptionally met with as a small tree; but its brilliantly coloured capsule and seed render it a conspicuous object in hedges and copses in autumn, and its beautiful evergreen congener, *E. japonicus*, lends it a claim to be included in this place. *Euonymus* numbers probably nearly a hundred species, whereof about sixty inhabit China and Japan. Our indigenous species is widely spread in Europe, and extends to North Africa and West Siberia. A few species are native in North America southward to Mexico and Nicaragua. The genus is more numerous represented in the mountains of India; a few species occur in the Malayan Peninsula, and one exists in Queensland, Australia. *Celastraceæ*, the family to which the genus *Euonymus* belongs, consists of at least 450 species of shrubs and trees scattered over the most widely distant tropical, subtropical and temperate regions.

The Lime (*Tilia*).—*Tilia* is restricted to the Northern Hemisphere, by recent species, in a natural state. Three species occur wild in England, but it is doubtful whether any species is really indigenous. *T. parvifolia* is found in old woods, and may have reached this country independently of human agency. At least twenty species of *Tilia* are now known, a dozen of these inhabiting China and Japan. The genus is scattered over the temperate regions of Europe, Asia and North America, one or more species occurring in the mountains of Mexico, within the Tropics. So far, it appears no species of *Tilia* has been discovered in Formosa. The family *Tiliaceæ* comprises a considerable number of genera and 350 to 400 species, mostly natives of warm and tropical countries. None inhabits frigid regions.

The Maple (*Acer*).—*Acer campestre*, the common Maple, forms a small tree under favourable conditions, and the Sycamore (*A. pseudo-platanus*) is now so widely naturalised in the United Kingdom as to justify the inclusion of the genus in our forest trees. Both are widely spread in Temperate Europe and Western Asia. Upwards of 100 species of *Acer* are on record, recent explorations in China having largely added to the number previously known. They are spread all round the north temperate zone, and most numerous in North America and Eastern Asia. Two species have been collected in North Mexico, and the

genus reaches the Southern Hemisphere in the mountains of Java. There are probably not fewer than fifty species in China and Japan combined. No species is known to exist in Africa south of the Atlas Mountains. The genus *Acer* was formerly referred to the *Sapindaceæ*, but it is now generally given family rank—*Aceraceæ*. *Dipteronia* is a new type of the family native of China.

The Ash (*Fraxinus*).—Between forty and fifty species of *Fraxinus* have been described, about twenty of which are recorded from China and Japan. Many of these are very elegant. The remainder are dispersed all round the rest of the north temperate zone, including North Africa and North Mexico. The Ash belongs to the same family—the *Oleaceæ*—as the Jessamine, Lilac, Privet and Olive.

The Guelder Rose and Wayfaring Tree (*Viburnum*).—*Viburnum Lantana*, the Wayfaring

a dozen species of coarse herbs, shrubs and trees, scattered in the most distant parts of the world, though absent from many countries. The common Elder is widely spread in Europe and North Africa, and it is naturalised in some other countries, including New Zealand, sometimes forming thickets. Two species of *Sambucus* are peculiar to Eastern Australia, one ranging from Queensland to Tasmania. Several species inhabit China, and one of these, *S. javanica*, ranges from Eastern India through the Malayan Peninsula to Java. A species of the affinity of *S. Ebulus* has recently been discovered in the mountains of East Tropical Africa. The genus is also represented in North America and southward through Mexico and the West Indies to the Andes and Eastern South America. *Sambucus* belongs to the *Caprifoliaceæ*, the same family as *Viburnum*.

Exotic Genera.—A few exotic genera of trees are as familiar as, or more so than, some of our

A VIEW OF LOWTHER CASTLE FROM THE FLOWER GARDEN.

Tree, rarely exceeds 20 feet in height, and is oftener seen as a bush; and the Guelder Rose, *V. Opulus*, is usually a bush; but some of the exotic species are of larger dimensions. Both *V. Opulus* and *V. Lantana* extend eastward to China, and the former is also at home in North America. Recent explorations in Western China have resulted in the discovery of between thirty and forty new species of *Viburnum*, bringing the total up to something approaching 150. *Viburnum* ranges all round the north temperate zone, with southern extensions in America to the West Indies, Mexico and Costa Rica to the Andes, and the genus is also represented in Central Madagascar. It belongs to the *Caprifoliaceæ* or Honeysuckle family.

The Elder (*Sambucus*).—*Sambucus nigra*, the common Elder, is not a timber tree; but it has the habit and dimensions of a small tree, and it is a familiar object in the South of England, at least. The genus *Sambucus* comprises about

native trees. Some account of the commonest follow here:

The Plane (*Platanus*).—Two kinds of Plane are not uncommon in cultivation in this country, namely, *P. orientalis* and *P. acerifolia*, the latter being almost exclusively the one planted in town avenues. A third, *P. occidentalis*, a native of North America, is less hardy and exceedingly rare in this country, at least in an adult stage. *P. orientalis* is a native of the Eastern Mediterranean region, eastward to the Himalayas. *P. acerifolia* is supposed to be of artificial origin. Besides *P. occidentalis*, which ranges from Canada to Mexico, on the Atlantic side, there are four other Mexican species. Mexico is the southern limit of *Platanus* and the seat of its greatest concentration of species. Fossil remains of plants, referred to *Platanus*, occur in Europe and Greenland in cretaceous to tertiary formations. This genus is another of those almost exclusively confined to North America and the Mediterranean region.

The Sweet Chestnut (*Castanea*).—As usually limited *Castanea* consists of two species, namely, *C. sativa* (syn. *C. vulgaris*; *C. vesca*), the Sweet Chestnut, and *C. pumila*, a native of South-Eastern North America; but some botanists reunite *Castanopsis* with it, and this comprises some thirty or forty species, perhaps more. The native country (or countries) of *C. sativa* is uncertain, as it has been widely cultivated from early times and many noble examples exist in this country, mostly in parks. Asia Minor has been suggested as its original home; but China seems to have equal claims, and the Sweet Chestnut probably had a wide prehistorical area.

The Horse Chestnut (*Æsculus*).—The genus *Æsculus*, including the North American *Pavia* and the Central American *Billia*, comprises nearly a score of species, most numerous in North and Central America, and one species is found in Colombia, South America. In the Old World, *Æsculus* ranges from South Europe, through Asia Minor, Persia, and the Himalayas to the Malayan Peninsula and China. Until within comparatively recent years, the native country of the Horse Chestnut was uncertain; but it has now been established, apparently beyond question, that it is truly indigenous in North Greece and in the Caucasus.

An Analysis of the foregoing paragraphs reveals the fact that the twenty-three genera of native trees range all round the Northern Hemisphere, across Europe, Asia and America, and, with the exception of *Betula*, *Carpinus* and *Tilia*, also extend to North Africa, at least. Nine of the twenty-three genera reach South America, mostly crossing the Equator. *Quercus*, so abundant in the mountains of Mexico and Central America, is the most notable exception, none apparently being recorded south of Colombia, the so-called Oaks of Chile being Beeches. *Ilex*, *Fagus*, *Euonymus* and *Sambucus* are elements in the Australian flora, and *Fagus* is an important constituent in the forests of New Zealand. And in tertiary times *Quercus*, *Betula*, *Alnus* and *Salix* flourished in Australia; providing always that the fossils have been correctly referred to these genera. In relation to climate, it may be repeated here that different kinds of Willow inhabit regions of the most extreme climatic conditions, from the Tropics to the northern limits of phanerogamic vegetation. A species of Poplar occurs in tropical districts of East Africa, and a large number of different Oaks are characteristic of tropical forests in Eastern Asia. These and other facts point to the former universal distribution of certain successive types of vegetation.

VENTURES IN FRUIT WALLS.

BY THE REV. JOSEPH JACOB.

QUITE recently one of that curious tribe of peripatetic school showmen called on me to prefer the usual request for the use of our day school for an evening entertainment, as he wanted to show a series of war pictures. We had a few minutes' conversation about what was taking place in Europe. Quite casually, as if it were an everyday occurrence, he mentioned certain inventions which he said he had passed on to the powers that be, and he presumed would soon be in daily use. One was a simple method of destroying Zeppelins

the ripening of fruit which in "cold summers" and "difficult years" would not come to perfection; or in the case of Peaches and Apricots, even in normal seasons, would barely ripen at all; is there any way of helping the wall to do its work? Is it feasible by any fairly simple method of construction to make a wall out-wall itself?

Readers of *THE GARDEN* may remember the diagram of an enclosure full of zig-zag lines which appeared in the issue for March 15, 1913, and which represented the foundations of walls which the present owner of Hadham Hall, Herts, found when investigating the cause of the failure of some Apple trees in (as the same enclosure now is) his kitchen garden. It was suggested that it may have been the site of a vineyard. I am unable to find in the old books at my command any direct evidence for or against this view. On the whole I am inclined to doubt its being a vineyard, for

I have never come across any instructions for training Vines, when planted in quantity, in any other way than on poles. In one of the war numbers of *Le Jardin*, an Apricot garden of olden time has been depicted. It consisted of a series of walls built in such a way as to get a maximum of sun. Were the zig-zags at Hadham for Peaches or Apricots, I wonder; or might they have been for Quinces? Sir Hugh Platt, writing in 1600, says: "Quinces growing against a wall, lying open to the sun and defended from cold winds, eat most deliciously. This secret the Lord Darcey brought out of Italy; quare, would this suit all other fruits?" Before the century was far advanced, fruit gardens in contradiction to orchards appear as highly desirable appurtenances

THE SEMI-CIRCULAR FRUIT WALL SUGGESTED BY LANGFORD IN 1681.

by means of a very unstable compound, which would explode with terrific violence on contact with their thin silk covering, but which, with proper precautions, would be perfectly safe for the users. As he explained it, it was all so simple and so efficacious that I ventured to remark that I wondered how it was he was still obliged to go on with his show. He explained that he had given his idea free and gratis to the Government for the good of the country. I collapsed. How many similar simple epoch-making inventions have there been in the past!

Fruit walls have not escaped the sanguine inventor. At various periods and in diverse ways attempts have been made to increase their efficacy. Some of these schemes have had only a butterfly existence, others have had a much longer life.

The proposition has been: Granted that the purpose of a wall is to make possible or to accelerate

to all houses of any importance. Here were the Apricots, Peaches, Nectarines and the choicer varieties of Pears and Cherries. How to get better and more certain crops must have been a perennial subject of thought to the gardeners of the seventeenth and eighteenth centuries. In the early years of the latter, according to Bradley and Switzer, the building of "hot-walls" began to be practised. It was at Belvoir Castle and Knowsley Park that these structures first saw daylight, and their success was such that the custom was continued till well on in the eighteen hundreds. Thus Loudon in his "Encyclopædia of Gardening" (fifth edition, 1827, page 305) writes: "Where wall fruit is an object of consideration, the whole of the walls should be flued or cellular." Some of these structures are still standing in many an old garden, but I have never seen one in use. A lifetime of about 150 years may fairly be claimed in this

connection to be a successful one. Hot-walls have been the great exception among the many attempts of out-walling fruit walls. For, whereas the sloping, the hinged, the circular, the waved, the horizontally tiled and various other forms have from time to time been tried, after a few years' use they have been found wanting. The hot-wall alone lived. It had, be it remembered, a good send-off. The number of bricks required was no more than what would be used for one a brick and a half thick. The cost of upkeep was not great. "The expense of warming walls of several hundred feet long will scarcely amount to thirty shillings per annum" ("Treatise of Husbandry and Gardening," Bradley, Vol. II., page 30). So it came to pass that hot-walls became general in the larger gardens; and various authors have from time to time recommended their use. Improvements in construction duly followed, also in their management. For example, James Justice in his "British Gardeners' Director" (1764) advises any length of hot-walling to be divided into three, so that the trees might always have two years' rest, "for continual forcing of one and the same space of walls will never do."

The following are among the varied methods which have been suggested for the better construction of walls for fruit trees, the idea being to get more work out of the sun.

1. The hot-wall, which has been the only really practical one.

2. The semi-circular (or angular) wall.—This was suggested by T. Langford in his "Plain and Full Instructions to Raise Fruit Trees in England" (1681, second edition 1696). The illustration in his book, reproduced on page 628, gives us a good idea of the kind of wall he advocates. "By means of these rounds, every wall will one time of the day or other have a share of the sun . . . and the trees be more secure from winds." Although the author says he has seen the benefits of such a wall in "somewhat a cold country," posterity condemned them, for the wind is "reverberated with great force upon the trees; the air is made colder, and fruit is thereby made later in ripening and becomes ill tasted."

3. Walls with arched foundations.—The idea was to give more root run. The practical result was to keep the fruit always growing, so that the hottest rays of the sun are powerless to ripen it, and it remains "a globe of undigested matter."

4. Inclined walls of either wood or brick.—Walter Nicol, at the end of the eighteenth century, advocated these made of wood, but they had been constructed nearly 100 years earlier, N. F. De Douillier having published a work entitled "Fruit-walls Improved by Inclining Them to the Horizon." Some were erected on this plan at Belvoir Castle and were visited by Switzer, but he found them

unsatisfactory. Miller and Lawrence also condemn them.

5. Horizontal shelters of tile or lead.—Lawrence seems to have been the father of the lead ones. In a "Kalendarium Universale, or Gardeners' Universal Calender," published with the imprimatur of Bradley, in the second edition (1733), page 90, details are given of how to build a wall with rows of tiles projecting $1\frac{1}{2}$ inches every few courses of brick. "To avoid the unseemliness of branches riding over the edges of tiles in each row, at convenient distances must

urge that fruit walls should be painted black. His criticism is short and to the point: "this also answers better in theory than in practice."

7. Mud or clay walls.—These are mentioned because I have somewhere read that the best way to make suitable provision for training trees against them was to stick plenty of sheep's bones in the clay (?) arranged so as to protrude a few inches from the surface, to which the branches might be tied. I have heard of an economical hostess who in this war-time requests her guests not to mess up the bones on their plates, as they are wanted for soup!

What a saving of leg of mutton bones there must have been in establishments when, in olden times, a mud fruit wall was in contemplation! But what changes since these things were!

It is no longer Helios but Vulcan that we want to make more useful. We have vineries, Peach-houses and orchard houses galore. We have nearly got all we can out of the sun—our chief concern now is fire.

TWO FINE APPLES.

Of late, much has been written of Apple Bramley's Seedling. Many competent growers hold the opinion that it is the finest culinary Apple extant, and undoubtedly it possesses merits which go far to support that opinion; yet I venture to suggest that Newton Wonder has serious claims to the premier position among culinary Apples. Every fruit garden should be well stocked with both varieties; they are cooking Apples in the truest sense of the word, the fruits are of good size and have a fine appearance. The trees are disease resisting and of very free growth, will grow equally as well in the orchard as in the garden, and both are heavy croppers; but here in Gloucestershire we find that, whereas Newton Wonder never fails to carry a very heavy crop, Bramley's Seedling bears abundantly in alternate seasons; that is to say, every second year the crop will be moderate, not a failure. We have an orchard here, planted some eighteen years ago, which bears ample testimony to the high qualities of both Apples. Many of the best varieties were planted, but the two Apples under notice are much in evidence from their sturdy

growth, cleanliness and fine shape; and this year, from one tree of Newton Wonder, we gathered three bushels of fine fruit, large and beautifully coloured; this does not include small or indifferent Apples.

Both are suitable for espalier or bush trees for the garden or for orchard standards. Perhaps Newton Wonder is rather better as a trained tree, Bramley's Seedling being of slightly more vigorous growth. If restricted to two main crop culinary Apples, one could not do better than plant both, and of the two I would give the palm to Newton Wonder

Cirencester.

RALPH E. ARNOLD.

APPLE NEWTON WONDER. NOTE ITS FRUITFULNESS ON THE YOUNG TREE.

be left void places or gaps for the wood branches to pass through . . . By the help of these kinds of shelter in the most difficult year a good quantity of the choicest fruit may be depended upon." Lawrence's substitution of lead for tiles enabled the shelter to be turned up or down at will. (There is a picture of this in the second part of "The Art of Gardening," by Lawrence, second edition, page 78.)

6. Painting walls black.—The well-known fact that a black surface is warmer to the touch than a white one led people in Philip Miller's time to

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Melons.—If ripe fruits are desired by the end of April, a sowing may be made early in the New Year. Sow the seeds in 2½-inch pots filled with loam mixed with mortar rubble. Plunge the pots in a hot-bed and place sheets of glass over them. To be successful with the cultivation of early Melons, a heated pit with a southern aspect is necessary. After it has been thoroughly cleansed, a hot-bed must be made on which to grow the plants, and this must be elevated as near to the glass as practicable. On this may be placed a bed of soil consisting of loam, brick rubble and wood-ashes. This must be made quite firm, or the growth of the plants may become gross and liable to canker. When the young plants are ready, plant them out on small mounds about 20 inches apart. A temperature of 65° or 70° must be maintained to keep the plants progressing satisfactorily.

Strawberries in Pots.—As soon as the flower-spikes begin to show, the plants must be placed quite near to the glass and the temperature raised to 55° or 60°. At this stage a little stimulant must be afforded, increasing it in strength as growth develops. Soot-water and diluted farm-yard drainings will be sufficient till the fruits have set, when a little artificial manure may be supplemented. The plants must be well sprayed with lukewarm rain water twice daily, and the atmosphere kept moist by frequently damping the bare surfaces in the house. Further batches of plants may be placed indoors at regular intervals.

Plants Under Glass.

Calanthes.—When the early flowering varieties have been relieved of their flower-spikes, the pots may be placed closely together on a shelf near the glass in a temperature of 50° or 55°. The roots should not be shaken out till a week or two before potting-time. The variety *sanderiana*, which is just now developing its flowers, must be given plenty of light and the atmosphere kept dry. In the event of the glass becoming obscured owing to fogs, it must be cleaned immediately, or the flowers will suffer.

Gardenias.—The plants growing in pots must be liberally fed with stimulants now that the flower-buds are developing. A temperature of 65° or 70° must be maintained, except during spells of very severe frost, when 5° lower may be allowed. Before coming into flower the plants may be laid on their sides and vigorously syringed with an insecticide, especially if they are infested with mealy bug.

Salvia splendens.—A few of the most promising of these must be kept for supplying cuttings. Place them in a cool, light house after partly cutting them down. *Salvia Pitcheri* may be cut right down and placed in a cold frame. This variety will produce plenty of cuttings from the base of the plants. These will root readily in cold frames in the spring.

The Flower Garden.

Bedding Plants.—Cuttings of *Pelargoniums*, *Coleuses*, *Iresines*, *Ageratums*, *Salvias* and *Lantanas* which were rooted in boxes in the autumn may now be potted into small pots. The propagation of various bedding plants must receive attention early in the New Year. Old plants of *Fuchsias*, *Lantanas*, *Marguerites*, *Salvia Glory of Zurich*, *Heliotropes*, *Iresines* and *Ageratums* may be placed in a warm, moist house, where they will make suitable growths for cuttings.

Calceolaria amplexicaulis.—This makes a most effective plant when grown as a standard, and it is so easily grown that a good batch should be propagated annually for this purpose. Some of the most promising of the young plants which were rooted in cold frames may be dug up and potted into 4-inch pots. Place them in a light position in a house having a temperature of about 50°. They must be staked, and, as growth proceeds, the side shoots must be removed till the desired height is reached. The plants will need a second potting into 6½-inch or 7-inch pots.

Annuals in the Flower Garden.—A well-arranged border of annual flowers provides a most

interesting and showy feature in the flower garden. The following are a few which are suitable for this purpose: *Larkspurs*, *Clarkias*, *Godetias*, *Cosmea*, *Coreopsis*, *Cornflowers*, *Dimorphotheca*, *Dianthus*, *Eschscholtzias*, *Linums*, *Nemesias*, *Salvia Fireball*, *S. Blue Beard*, *Nigellas*, *Kochias*, *Arctotis*, *Lavateras* and *Sunflowers*. *Antirrhinums* may be treated as annuals by sowing the seed in heat in February. The ground should be prepared now, and a good quantity of well-rotted manure be dug into it.

The Hardy Fruit Garden.

Peaches and Nectarines.—These may now be pruned and cleaned. If the old fruiting wood was removed when the fruit was cleared, little remains to be done now, but it will be wise to examine the trees carefully, and in the case of very old trees it is sometimes necessary to cut out an old branch here and there to make room for young wood. The trees will need a thorough washing with an insecticide; and should they be attacked by scale, a soft brush must be used to dislodge it.

The Fruit-Room.—Apples and Pears should be examined once a week, and those which have commenced to decay must be removed. Endeavour to keep the room sweet by opening the ventilators during mild weather. A temperature of 40° will be suitable for Apples; and if very severe frost sets in, the windows and doors should be covered with mats.

The Kitchen Garden.

Cauliflower.—About the first week in January a sowing of an early variety may be made. Sow the seed thinly in boxes of light soil and place them on a shelf in a light house. *Sutton's First Crop* is an excellent variety for this sowing.

Seakale.—To keep up a supply of this vegetable, a batch of roots must be placed in the forcing-house every week. The roots outdoors must be covered with Bracken or litter as a precaution against a continued spell of hard frost. When lifting the roots for forcing, select the pieces suitable for cuttings and place them in a cool shed. In wet weather they may be cut into suitable lengths, bunched up, and placed in an upright position in boxes. Cover them with a few inches of soil and place the boxes behind a north wall.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Plants Under Glass.

Chrysanthemums.—The majority of the cuttings should now be taken, to allow a number of the old plants to be thrown away, and so leave more pots and space available for other material. Cuttings which are already rooted should be gradually accustomed to more air, which is essential if sturdy and strong plants are to result. Any cuttings attacked by fly should be dipped in a mixture of insecticide.

Stove Temperatures.—Too much artificial heat is injurious at this period of the year, when the majority of plants should be resting. *Crotons* and other occupants of the plant stove invariably start more freely into growth at the proper time if they have had a proper rest. This must, of course, be done with discretion, as too low a temperature or a continuation of cool treatment would in most cases cause the leaves to drop and the general disfigurement of the plants.

Tree Carnations.—This is the best time of the year to propagate these plants. Every available cutting should be secured as soon as possible. Cuttings already rooted must be potted up singly in 2-inch pots and kept in a close frame for a few days until the roots commence to take possession of the soil, which should be light and open, made so by the free addition of crushed brick, charcoal, leaf-soil and coarse silver sand. Be careful not to over-water, as the small, tender roots are quickly injured if water is given in excess.

Malmaison Carnations.—The potting of young plants into 6-inch pots should be completed as

soon as possible, seeing so much is to be gained by doing this now. Maintain a temperature of 50° during the night, and only allow an advance to 55° during the day. If rust is troublesome, remove the badly affected parts, and on no account allow a moisture-laden atmosphere, as this would be ideal conditions for rust becoming firmly established.

Fruit Under Glass.

Bottling Grapes.—After this date, if only for the welfare of the Vines, no Grapes should be left hanging in the vineries. Although all the foliage may have fallen, the Vines are being robbed needlessly if the bunches are left to hang. Shrivelling is common with late Grapes, especially *Mrs. Pince*, but this will be prevented considerably if the Grapes are bottled. A dry and cool room, where there is not much chance of dust being present, is the best place to keep them. The bunches must be looked over occasionally to remove any decaying berries, which would quickly infect others and so spoil an entire bunch.

The Kitchen Garden.

French Beans.—More sowings should be made as the days lengthen, seeing they grow better and produce pods more freely. White and green fly must be kept in check by fumigation. To prevent red spider becoming troublesome, the foliage should be syringed when the conditions of the weather will permit of it being done.

Rhubarb.—Where a continuous supply of this is required, fresh batches should be brought into heat every fortnight. Where indoor accommodation is limited, a few old barrels with the ends knocked out can be placed on the plants outdoors and surrounded with new stable litter.

Asparagus. like Rhubarb, should be brought indoors to force at intervals to keep up a regular supply. Unlike Rhubarb, it should be grown in full exposure to light.

Salads.—Chicory and Endive must be blanched as required for use, allowing about a fortnight for the process. Lettuces become scarce at this season, so that a few seeds may be sown at once in boxes, which will be growing on and be ready for pricking out in frames for spring use.

Carrots.—Young, tender roots being in demand the whole year round, more seed should be sown. Where frame space is limited, some boxes may be requisitioned, so long as they are 4 inches or 5 inches in depth. This is also a very profitable way to grow young Carrots, as, after growth is advanced, they can be readily removed to make way for other plants.

Cucumbers.—As the plants at present in bearing will become exhausted within the next few weeks, seeds should be sown in brisk heat to produce young plants to replace them.

Tomatoes.—Young plants should be kept in a growing temperature of 60° where there is not too much moisture. As soon as the roots have taken possession of the soil, pot on into larger pots, but do not use those too large. Small pots are to be preferred for all the early crops.

The Flower Garden.

Standard Heliotropes which are to be used for summer bedding should be kept growing in a stove temperature. Continue to remove flower-buds and all side shoots until the desired height is attained. On the slightest appearance of fly, a fumigation should be given. When repotting, do not shift into large-sized pots, as splendid specimens can be grown in those of 5 inches with the assistance of a little artificial manure.

Digging and Trenching.—Any vacant beds or borders should be dressed with manure, and either dug or trenched as time and the conditions of the weather permit.

Sweet Peas.—The young plants which resulted from seed sown during the autumn should be kept well ventilated, whenever possible. Staking with small canes will also be necessary. If it has been decided where they are to be grown during the coming season, a deep and wide trench should now be thrown out, leaving the soil thus exposed for the remainder of the winter.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, *Castlemilk Gardens, Lockerbie, N.B.*)

BORDER CARNATIONS.

I HAVE had several long and interesting letters from correspondents and some personal friends regarding my selection of two dozen border Carnations specified in the issue for November 27. As anticipated, and as I had hoped, a good deal of friendly criticism is launched; but it is pleasing to note that the consensus of opinion is that the varieties named would be hard to beat as an all-round lot. Let me analyse, first of all, the comments of a noted grower and exhibitor from North London. He has not grown Beau Nash, Ibis, Zulu or Ziska, so cannot speak with authority on their merits. Bookham Clove and Miss Rose Josephs he knows well by reputation, but does not include them in his stock because he does not particularly fancy the colours; and he thinks I made my only real mistake by naming Solfaterra as my third yellow. I quite expected opposition to this last, and agree that it is somewhat tall in growth and is not so fine a flower as Daffodil. On the other hand, it has a grand constitution, which Daffodil has not, although it was included in my list because of its pre-eminence for exhibition; while Border Yellow goes in on account of its good colour, wonderful vigour, and strength of stem. But its flower is not refined enough, while that of Solfaterra is both shapely and a real golden yellow.

My correspondent thinks Mrs. Elliot Douglas might have been named instead, and—well, so it might, quite easily; they are both highly finished products of the hybridiser's art. Beau Nash is a very fine new Carnation, of strong, robust growth, doing excellently in the open border, and has an absolutely brilliant colour of pure deep rose pink. Ibis is a Miss Willmott in scarlet, with more substance in the flower than the old Bob Acres, and it does not burn in the sun. I am surprised Zulu has not yet been tried by this grower. I consider it quite the best of the dark maroons, and, like Miss Rose Josephs, it continues to give perfectly shaped flowers for about four months. Ziska I myself have not grown, but Mr. Douglas recommends it for its unusual colour—cinnabar red—and good form, and I have secured it for next year's bloom.

Everyone ought to grow Bookham Clove for its scent alone; but, apart from that, the flowers are an immense advance on the Old Clove in every way. Miss Rose Josephs is, in my own judgment, one of the most beautiful of all flowers, and I simply cannot understand anyone not liking it. The colour is difficult to portray by description, but I suppose it is old rose. It is a real "Liberty" art shade, and I know of no other flower in garden or greenhouse that can claim a similar tint. Vieux rose has, of course, already appeared among Carnations, as, for instance, in Unique; but when it first made its advent the growth of the plant was weak and very dwarf, and not till Unique

came on the scene could Mr. Douglas find grass strong enough to make plants that would satisfy the public. But Miss Rose Josephs beats all its forerunners, for here we have health, sturdy growth and a perfectly formed flower that is unique indeed.

Another correspondent asks why I made no mention of Cardinal, Becky Sharp, The Bride, Rony Buchanan and Droitwich. The only answer I can make to this is that I do not consider these varieties have been able to stand against the winnowing influence of the survival of the fittest. Rony Buchanan is certainly a good fancy for border cultivation, but there is nothing very distinguishing about it, and there are finer fancies

from Edenside this autumn. I saw it at the Carnation show in July last, and thought it one of the most striking novelties ever produced from that famous nursery. The ground colour is very pure, and is closely barred and streaked with bright deep red; while the petals are broad and smooth, making a noble flower of dignified proportions. For those who can satisfy their natural craving—which, I think, is common to all horticulturists—for novelties, I can strongly recommend Centurion, a new yellow-ground fancy; Henry Brett, a large crimson maroon self; Salmonea, salmon pink, very sturdy constitution; and Sweet Anne Page, a most beautiful flower of delicate colouring, lavender markings on a pale yellow ground. The illustration depicts the new fancy Carnation Edenside, one of the best in this section ever produced. J. L. GIBSON.

THE NEW FANCY BORDER CARNATION EDENSIDE.

now on the market. Cardinal, too, has been improved upon, and Becky Sharp is, if I mistake not, simply a sport from Lord Steyne, which has appeared in several collections, and it is a notorious burster. Droitwich is a white-ground fancy, and when at its best is a dainty-looking flower. As a rule, however, the white ground is not pure enough in tone, not so good as The Bride in that respect, while even the last named will go down before Daisy Walker. Personally, I like Montrose if a second white-ground fancy is wanted in a small collection, and its grass is always clean and healthy looking, making very fine layers.

A new variety in this class that is sure to be largely grown is Lord Kitchener, sent out

flowering qualities, while no difficulties will present themselves in respect of cultivation. The repotting should be done in early spring, or soon after the flower-spikes are removed, using as a rooting medium good fibrous loam, peat and sphagnum moss in equal parts, while a few small nodules of charcoal or finely broken crocks may be added with advantage. Owing to the thick, fleshy roots, ample pot room is necessary, and the pots should have one-fourth of their depth filled with drainage; over this may be placed a thin layer of moss to maintain a free outlet for water. After being disturbed at the base, little water will be needed for a week or two; but when the roots begin to take possession of the soil, more may be given, and at no time must they be allowed to suffer from

A USEFUL WINTER-FLOWERING ORCHID.

ZYGOPETALUM MACKAYI.

THIS fine Orchid was originally introduced from Brazil in 1826, and has always been held in high esteem by cultivators generally, while a good batch is often seen in gardens where there is no other attempt made to grow Orchids, perhaps excepting the Cypripediums. Many plants have been imported, but a large number have also been raised from seed in this country. Z. Mackayi has been carefully fertilised with pollen from such genera as Odontoglossum, Lycaste, Cymbidium and Maxillaria, but the seedlings, upon flowering, were in every instance Z. Mackayi pure and simple. Mendelians will probably say that if these seedlings were "selfed" a hybrid would appear in the proper ratio; but this has been carried out even to the third and fourth generation by several Orchid-growers without any trace of the pollen-bearing parent being apparent. The spikes of this fine Zygopetalum are produced during the autumn and winter months, and the somewhat flat flowers are light yellow-green, blotched with purplish brown, while the broad, fan-shaped lip is white, streaked with violet purple. One reason why this plant is popular is, no doubt, owing to the facility with which it adapts itself to the conditions prevailing in greenhouses and its free-

drought. Z. Mackayi may be grown either at the warmest end of the cool house or in the intermediate division, while some place them among the Cattleyas; but a little more shade is required to secure the best results. The principal pests are thrips, which congregate in the new shoots; but these can be destroyed by vaporising the house at intervals, or by spraying with a weak solution of some reliable insecticide. T. W. B.

WAR NEWS FROM FRANCE.

FRENCH horticulture has been severely tried by the great war. Many gardeners and nurserymen have been killed or wounded at the Front, some of whom, of course, are not known here in England, but others who have lived among us and who have many English friends have also suffered.

At the present moment one well-known name stands out prominently before us. M. Henri Nonin, only son of our old friend M. Aug. Nonin, the well-known Chrysanthemum grower near Paris, has been wounded a second time. Early in the war he was struck by a piece of shell and wounded in the leg, and subsequently contracted typhoid fever. After five months' absence he rejoined his regiment, and shortly afterwards was given a commission. Sous-Lieutenant Nonin, as he now is, was again wounded at Toul, where his right arm was broken and badly splintered. It is hoped that his arm will be saved, but at least eighteen months will elapse before he can expect to regain the use of it, if ever he does. We are pleased to record that on the 3rd inst. our young friend was decorated in hospital at Lyons with the Legion of Honour and the War Cross.

M. Alfred Nomblot, who was recently appointed to fill the place of M. Abel Chatenay as secretary of the National Horticultural Society of France, and was wounded on April 18 last, but, refused to leave his regiment, has now been promoted to the rank of Chef de Bataillon. He, too, mentioned in the order of the day, has received the War Cross.

M. Lucien Gravereau, son of M. A. Gravereau, belonging to the French Colonial Ambulance Service, has received the same distinction for gallantry at the Front. English visitors to Paris are well acquainted with this young man's father, who is familiarly known as Gravereau without the "x," to distinguish him from the famous rosarian, M. Jules Gravereaux of L'Hay.

We learn that M. René Adnet, eminent for his work in the improvement of the Gerbera, who lost the use of his arm, but, nevertheless, continued his service as captain instructor in his regiment, has had a serious attack of congestion of the brain as the result of overwork. He is now reported as improving.

M. Montigny, a prominent exhibitor of new Chrysanthemums, living at Orleans, is reported to have died recently. His son, who spent some time in England a few years ago, was one of the first of the young French gardeners we knew personally to be killed in the war.

From a paragraph in a French contemporary it appears that it was not M. Joseph de Hemptinne, the orchidist of Ghent, who was executed, as stated by the *Echo Belge*, by the Germans a

short time since, but his brother, Count Paul de Hemptinne. M. Joseph de Hemptinne, it is said, was condemned to death, but was pardoned on the intervention of the Pope.

OBITUARY.

THE HON. JOHN R. DE C. BOSCAWEN

AS announced in our last issue, the Hon. John Boscawen of Tregye, Perranwell, Cornwall, died suddenly on the 12th inst. For a long time he had taken the greatest interest in everything that pertains to horticulture, and his cheery and exhilarating presence will be missed in many circles. His services were continually requisitioned for our large shows, including, of course, the International.

He was one of the founders of the Cornwall Daffodil Society in 1897, and from that time until

THE LATE HON. JOHN DE C. BOSCAWEN.

the present he was its honorary secretary. The fame and success of this—the pioneer—society have been greatly due to his enthusiasm. He had a fine collection of Daffodils in his garden, and his wife, Lady Margaret, has been a frequent exhibitor at Truro.

He was one of the oldest, if not one of the original, members of the Narcissus and Tulip committee of the Royal Horticultural Society.

Latterly his public activities have been mainly directed to the development of the horticultural section of the "Royal." Visitors cannot fail to have marked its expansion within the last few years. We do not think we are overstepping the mark when we say that this has been due almost entirely to the energy, the business acumen, and the never-failing sympathy and courtesy of John Boscawen, its head.

We respectfully tender his widow and family our deepest sympathy in their great loss, which we, in common with all horticulturists, must to some extent share.

THE "COUNTRY LIFE" ANTHOLOGY OF VERSE.

IN the pages of *Country Life* all aspects of the country, its activities, sports and pleasures, are described. But mostly in its poetry is to be sought the imaginative side of life and rural beauty. During the course of years many poets of established fame have contributed to its pages, others who have since attained to distinction sent it their earliest verses, and, last of all, verses from unknown contributors have made their appearance in its post-bag from all parts of the world, and have been printed whenever individuality and fine taste were shown. The one criterion applied to them has been that of worth and sincerity. There are poems for to-day of "the lads who have gone to the war," and of those who will come back no more. The poems of loss and regret will appeal to the many who have heard the beating of the wings of the Angel of Death. And it is hoped that the beautiful poems of our countryside, of our grey seas and tumbling burns, will be read with joy by soldiers far from the home and land where their hearts are. Did space permit, we should like to quote a number of the poems on flowers and gardening, but we must confine ourselves to two. The first is

"SNOWDROPS.

Snowdrops, in springs to be
When popped dreams I keep,
Grow not over me
Lying asleep.

Else might I sadden when
Thy Elfin Melody
Waking Earth up again
Cannot wake me.

A. HEPPLE DICKINSON."

And the second

"THE POPLARS.

In stifling lane and garden bed
The flowers droop, listless in the heat,
O'er petals lying dead.
The Elms stand motionless. The Fir's
Hot scent hangs stagnant. No breath stirs
Across the shining Wheat.

But far above the flowers a-swoon,
And far above the silent sheaves,
From pallid dawn to languid noon,
The Poplar trees are whispering low
To little secret winds that blow
Among their murmuring leaves.
The Poplar trees are singing, throughout the sultry
hours—

Songs the cherished garden flowers
Will never, never know;
Songs the blessed harvest field will never, never
know—
Are singing to the little winds that flutter to and
fro.
ISABEL BUTCHART."

Nearly one hundred poets contribute to the pages of this excellent book, among whom we may mention Robert Bridges, Lord Archibald Campbell, Walter de la Mare, Sir George Douglas, Bart., John Drinkwater, Lady Glenconner, Dorothy Frances Gurney, W. E. Henley, Violet Jacob, Sir Henry Newbolt, Lady Margaret Sackville, Lady Wynford, &c. It is safe to prophesy a very large demand for this charming anthology.
